You might want to consider the Hustler 4,5 or 6 - BTV. Requires no guying and is easy to assemble (30 mins) and tune (15mins). It is sleek in appearance and with ample radials it is a very usable DX antenna on all it's bands.

Bandwidth, perhaps. Wide dynamic range? The FCC rules seem to
suggest otherwise.

I did the same after putting together a HF setup. The electronics was fun,
but the chirping was booorrring.

> But I vaguely recall a 5/8 wavelength antenna that had a good low-angle

I didn't know the height affected the pattern that much. IIRC 5/8
wavelength seems to be what the AM stations around here. Though they'd
load up a barn if it worked.

Hi OM,

The long and short of it (apropos of your antenna spec), is that your shorter antenna will need a new matching circuit (apropos of the smaller antenna's size) for the related issues of maximum transfer of power. The reasons for matching may vary (and with it, efficiency), but not so you would notice. If you did notice, then your production tolerance (if not customer application) variations will kill you in the marketplace (fact of life in a Kapitalistic world). No amount of armchair philosophies about Thevenin's theorem will replace that loss.

3077. ATAS-120 mobile HF antenna mount question

Newsgroup: rec.radio.amateur.antenna
Date: 2005-02-28 02:41:31 UTC
From: "Joe S." <nobody@nowhere.net>
Message-ID: <cvu0cb0k5f@news2.newsguy.com>
Source record: 81416

Okay, one more question about the Yaesu ATAS-120 before I order the FT-857 and ATAS-120.

How do I mount the ATAS-120? As I understand it, the antenna has a type M connector built into the base so it will screw into a standard SO-239 connector. The antenna is 53-plus inches high so I'll need a fairly sturdy mount.

I drive a small pickup with an aluminum cap on the bed. There is a ladder rack attached to the cap -- the ladder rack consists of 3/4-inch square aluminum tubing -- I can clamp a mount to the ladder rack but I really need an adjustable mount so I can lay the antenna down when need be. I have figured out how to tie everything together with ground straps to ensure good grounding to the frame but now I need suggestions on which mobile mount to use.

I was looking at some Diamond mounts but they all say not recommended for antennas over 45 inches high.

I could fabricate something out of thick sheet aluminum and galvanized corner brackets but a commercial mount would look a lot better.

Thanks.

I built my ATAS bracket out of aluminum. It was the only why I could find
to get something that would hold up. I broke a couple of Diamond antenna
brackets on my Motorcycle trying to hold up dual band antennas until I
built on from scratch.

3079. Proper Phasing of two Andrew DB224 Antennas

Newsgroup: rec.radio.amateur.antenna
Date: 2005-02-28 03:55:39 UTC
From: af4z@cfl.rr.com
Message-ID: <%CwUd.94017$pc5.93385@tornado.tampabay.rr.com>
Source record: 81418

I would like to install two Andrew DB224 4-element colinear antennas as a DB228 (8 element). When the antennas were ordered to replace a Celwave P654, I was told that two 224 and and the proper phasing harness would be the same. The antennas and harness were ordered but I have a problem. The antennas were shipped but I'm now told the phasing harness for the amateur frequencies (-007) is no longer available. I have received some information on the phasing harness but from the drawings provided, the two outputs are not the same length therefore will not be in phase. Since the antennas are the same, wouldn't the two outputs of the phasing harness be in phase or is it normal to provide some downward tilt. Unless I'm badly mistaken,the antenna element should be fed in-phase giving maximun gain in the horz.direction.

I get a lot of flack when I mention using a ground for my radio and antenna because of electrical code. I don't believe that my station causes a ground loop because of it's design, but there is the issue for other places as well.

First of all, I have a deep cycle battery for a power supply for my Icom 706 MKII. I use a smart charger to keep the battery charged. The charger only uses two wires. The radio is grounded through a lightning/static arrestor by way of the outer brass casing that screws into the SO-239 connector on the radio. My ground is a copper pipe stuck about 5 or 6 feet deep next to the window where the radio is located. A large wire goes from the radio to the ground-rod.

The reason I feel this does not create a ground loop, is that the only electricity is run through an isolation transformer (the charger) to the twelve volt battery which powers only the rig and an emergency light.

However, there are others with this issue. Assuming they have 'normal' stations, they are likely to have a 3-wire grounded power supply or a radio with a grounded power supply built in. For these people (and possibly me in the future) I am wondering about the best means of a ground especially when the rig is far away from the electrical panel.

My thought is to run a solid #8 wire underground from the electrical ground rod to the closest point to the radio. There, set an 8 foot ground rod giving a close to zero loss from the radio ground to the electrical ground. The fact that the copper lead between the two rods is buried will only improve the radio ground rather than create a resonant loop.

Any thoughts?

on several occasions i have had two cocks in my ass in-phase at the
same time. sometimes we use a double dong as a phasing harness.

3085. Re: G5RV (Yet Again)

Newsgroup: rec.radio.amateur.antenna
Date: 2005-02-28 05:04:34 UTC
From: Photoman <photomanxaa@hotmail.com>
Message-ID: <9KudnVznEZXMO7_fRVn-qg@adelphia.com>
Source record: 81274

After years of using a tri-bander and high inverted vees for 40 and 80 I found myself in a situation of putting up a G5RV through a auto tuner from my old TS-820S. It is only 30 feet off the ground and it is a shortened version I bought off Ebay. I figured I had a good dummy load but two nights ago I worked four stations on 75 meters in Europe with 100 watts from Virginia (on SSB) so I'm not so displeased. Got 59, 59, 58, and 59+15 reports. Maybe I can finish up 5Band DXCC after all!
Good luck & 73,
Ken

Tie them together at a common point. In one of the radio stations I worked at, I was always trying to second guess the engineer who was before me. There were plenty of grounds loops that the RF loved to bug us with. That was a 10KW AM'er, RF getting into an audio console was a real source of irritation for the production people as well as me. We resorted to screening one control room with copper screening. THAT was cool, we got 30 DB of isolation when the door was closed. Wish I had that screened room for my SHACK!!!!

Hi Buck,

You do not have a ground loop or avoid one because you are on or off the grid, or using a separate station ground system, even when bonded to the service entrance ground as code requires.

Grounding multiple pieces of equipment in series before the common ground is what allows ground loops. That can happen whether the building's three wire 120v system is the only ground, or a station ground is also involved. Avoid it by not daisy-chaining the bonds of individual equipments with the station single point ground. As awkward as it seems to individually bond equipment to the single point ground, this is how to avoid a ground loop. Practicality often overrides this design concept (using a bus-bar for multiple equipment grounding, etc). But if noise could be isolated as caused by such series-grounding, then you know how to eliminate it.

The station ground IS an awful thing to have, and a major cause of lightning damage to the station IF it is both: 1. separate from the service entrance ground, and 2. not properly bonded to the service entrance ground. We would avoid most of the outdoor grounding and bonding systems required to control this condition IF we just brought all antenna feeds into the structure AT the service entrance ground. And then shield grounded and used arrestors right there.

For HF-only feedlines (where an extra 40-60' of coax would add superficial loss) there should be no excuse for not bringing all feedlines into the structure only at the service entrance. UHF systems that suffer much higher line loss tempt us to bring antenna feedlines directly into the radio shack. THAT causes a major bonding headache. This is because we have to achieve such low impedance connections to the service ground that lightning will never choose a path up from ground, through our equipment, and out via the house wiring to get back to the service entrance ground. We are never fully protected from such occurrence if the station ground and service ground are apart from each other, no matter how well they are bonded. But we can be reasonably protected in that respect, when the bonding jumper is of significantly lower impedance than the AC wiring in the home.

#8 copper is no where near the "significantly lower impedance" we're talking about. Either wide copper strapping or #2 or #4 copper would be a better example for the bonding connection between service entrance and station ground. The more places along the way that bonding jumper is also bonded to the outdoor antenna ground fields, radials, etc, the better. Voltage division plays a big part when everything is bonded and many grounding electrodes are used.

Hope this helps,
73,
Jack Painter

True, but only in a linear system representable by a Thevenin source having a resistive component that is dissipative. But an r-f amplifier is a non-linear system with a non-dissipationless "internal resistance" and cannot be modeled with a Thevinin dissipative source.

IF the Thevenin source approach worked, we would have to be content with max 50% efficient amplifiers. We know we can do better than that substantially.

The latest QEX has a revealing examination of impedance and conjugate matching matters.

Bottom line seems to be that one concentrates upon the specific load *resistance* specified for all other specs to be met. Such a load permits the amplifier to deliver maximum power within specifications and as such is conjugately matched to its load.

Hi George,

I know you won't appreciate this, but it is a telling, simple test of
a practical situation with a practical Amateur grade transistor model
100W transmitter commonly available for more than 20-30 years now:
1. Presuming CW mode into a "matched load" (any definition will do);
2. Report the DC power consumed before hitting the key;
3. Report the DC power consumed while holding the key.

Concurrently note:
A. Report Heat Sink Temperature for a previously idle/rcv condition;
B. Report Heat Sink Temperature after 10 minute key-down.

For a hypothetical "100W" model (again, a contemporary, common example
for Amateur use) available through standard commercial venues:
2. About 20W - 30W
3. About 200W - 250W
A. About 20 degrees C (or room temperature)
B. Well above 37 degrees C (or skin temperature)

Now, if we are to be any judge of efficiency (Thevenin does not have
to be invoked, condemned, or venerated); then it runs close to 50%
(ï¿½10%). Others can invoke their favorite deity to explain.

Now, if we are to be any judge of dissipation (no requirement for
advanced degree); then heat as a loss by virtue of less than 100%
efficiency is quite evident. Others can invoke photons to describe
why.

To forestall any armchair engineers, yes, this efficiency is System
efficiency. However, I would be surprised if a practical common
Amateur grade transistor model transmitter commonly available for more
than 20-30 years now has any configuration that does not apply supply
voltage directly to the final transistors; and instead adds a
significant current path outside of this load (citations to available
schematics would be compelling, but any argument without this would be
speculation). It takes very little effort to subtract out the power
drain of the receive mode (being very representative of the similar
power demand of supporting circuitry for transmit up to the driver
stage). Barring such amazing evidence of a significant power drain
not found in the finals, it follows that a simple computation of

efficiency has its merit and has been met.

I still have my training wheels on, but I am trying to model the subject antenna, as described in the ARRL's Antenna Classics.

The feed end at ground level calls for a 9:1 transformer. The opposite end (also at ground level)calls for a 9:1 transformer with a 50 ohm dummy load attached. How would I include these in the model?

Thanks for your patience and help.

Bill

The maximum power transfer 50% efficiency Po/Pin figure is only valid
for a "linear" amplifier termed Class A (current flows through the
whole cycle). Other amplifier classes were invented which improved on
that 50%. i.e. Class B (push-pull) can approach just shy of 70%
(current flows through 50% of cycle), and Class C close to 90%
(current flow less than 50% of cycle). Did I misunderstand the
problem?

... which is not the definition of "plate (anode) efficiency"
from the IEEE Dictionary: "The ratio of load circuit power
(alternating current) to the *plate* power input (direct current)."
For amplifier efficiency calculations, only the DC power input
to the plate-collector-drain is considered, by definition. The
power dissipated in the surrounding support circuitry is not
included in the definition of "plate efficiency".

I would include a one-segment wire at each end to hold the source and
load. Use a 450 ohm load and set the alternate SWR Z to 450 if you
want to see the SWR normalized to that value.

This assumes that the 9:1 transformers don't add any reactive effects,
something you can't know anyway without some measurement
characterization.

Richard Clark, KB7QHC wrote:
"However, I would be surprised if a practical common Amateur grade transistor model transmitter commonly available for more than 30 years now has any configuration that does not supply voltage directly to the final transistors---."

My Kenwood TS-130S manual has specifications on page 2. Transmitter output impedance is specified as: 50 OHMS!

Om page 30 is a level diagram. Output from the transmitter`s low-pass filter is measured as 70.7 volts at 14.25 MHz, which is 100 watts into 50 ohms (square root of PR).

D-C power is fed to the center-tap of a push-pull output transformer to the final transistors.

From the specifications page also, the power reguirement is TX: 18A 13.8V DC. It`s a linear amplifier. Only 40% efficiency. The designer probably was more interested in low harmonics than efficiency. The final by itself only takes part of the 18A ao its efficiency is more than 40%.

Kenwood says its transmitter presents an impedance of 50 ohms at its "OUT" terminals in the diagram on page 30. 100 watts at 70.7 volts.

Best regards, Richard Harrison, KB5WZI

>From the specifications page also, the power reguirement is TX: 18A >13.8V DC. It`s a linear amplifier. Only 40% efficiency. The designer >probably was more interested in low harmonics than efficiency. The final >by itself only takes part of the 18A ao its efficiency is more than 40%.

Hi Richard,

My point exactly. However, how much more than 40% and how much of that 18A (248W) is not devoted to the finals? Your "typical" rig would most like be composed of a three stage design with 5W/20W/100W kind of progression - very common.

The manufacturer of your finals transistors would be quick to spec them with a ballpark of 45% efficiency (Class AB, in a CW application) in the best of circumstances for full power.

Perhaps someone else has better Pout/Pin figures for a commonly available, retail Amateur 100W multi-mode HF rig? Say like 13.8V @ 10A for 100W CW?

Again, appeals to deities are always amusing (say what you pray), but we are missing the photon (sic) explanation (see what you mean) to completely round this out.

right me old Hubert, don't know what the grief is for? The bloke asked a simple antenna question!

If you take and erect at ground level, two 1/4 wave vertical antenna elements,
spaced 1/2 wavelength apart.
Install a good radial earth.
Fit both vertical elements with 1/4 wavelengths pieces of 50 ohm coax cable,
Take both cables to a, 2 female / 1 male, pl259 T piece, in the middle at 1/4 wavelength .
The T out cable goes to rig.
Then take a 1/2 wave piece of coax with a PL female plug on one end, and a male on the other.
Insert this 'stub' between the vertical element and the T piece.
this make one side of the array feeder, 1/2 wavelength longer, making it 3/4 wavelength,
this will alter phase and direction from end fire, to broadside.

Clear as mud?

3107. Re: Unloaded Transformer

You may save a few kWh a year by unplugging such a transformer...or maybe not. How cold a climate do you live in? How do you heat your house? Would the energy spent plugging and unplugging it (and wearing out the socket so it has to be replaced sooner, with the associated consumption of materials and power to make new sockets, would that energy be better spent being a bit more diligent about turning off other much larger power consumers?

I wonder, considering how much electronics you buy in compact fluorescent lights, how much it would add to the cost of the transformer-type wall-warts to add a circuit to disconnect the transformer from the line when there is no load, or just use a switching design that draws very little power when unloaded.

Cheers,
Tom

Asimov wrote:
"The maximum power transfer 50% efficiency figure is only valid for a "linear" amplifier termed Class A (current flows through the whole cycle)."

Maximum power transfer does not care how many degrees of a cycle the power flows. Nor does it care whether the source is electronic. Whether it applies depends entirely on the behavior of the source and load.

It`s true that current in a linear Class A amplifier flows continuously and does not vary in average amplitude over a complete cycle.

When there`s no signal input to a Class A amplifier, its power input is volts x amps and its efficiency is zero. Maximunm undistorted output requires 1/2 the d-c input to the stage. As this power exits the stage, it cools as the remaining dissipation is only 1/2 the no-signal dissipation.

An amplifier can be a linear source without operating under Class A conditions. Higher efficiency is the main reason for not operating in Class A. By turning the amplifier devices off
for part of each cycle, efficiency can be raised significantly beyond 50%.

Best regards, Richard Harrison, KB5WZI

Insulation and dielectric properties are not the same things, are they? The volume resistivity of a material is particularly important in dielectric applications, but not necessarily so in insulation applications. PVC may be okay as an antenna insulator, but not so ok as a trombone trap dielectric. Phenolic is a good insulator, but not necessarily a good dielectric.

You say, "I have no way of actually measuring it." But I wonder about that. Certainly it's not too difficult to find the velocity factor with the simplest of equipment, and with a bit of creativity, you should be able to figure out the impedance as well. In any event, it's pretty common to make at least minor tweaks on matching stubs to get them to do the intended job. Will you have any way to know when it's doing its job properly? That in itself may be all the measurement you need.

Cheers,
Tom

3115. this single mom asking for help

Newsgroup: rec.radio.amateur.antenna
Date: 2005-02-28 21:54:41 UTC
From: gdfailin@westshore.edu
Message-ID: <1109627681.839265.63040@z14g2000cwz.googlegroups.com>
Source record: 81304

This is currently all over the web. I never thought I would do
something like this
but I just lost my job, I am a single mother of 4 sons, one in Iraq,
one in college and 2 still in school. I should be able to get
unemployment,
but the bills are piling up and I figured what can it hurt.
Gayle

THIS REALLY CAN MAKE YOU EASY MONEY IT WORKS !!!
BUT YOU HAVE TO FOLLOW IT
TO A LETTER FOR IT TO WORK!!!!
JUST AN INVESTMENT OF 6.00!!!
ITS THAT EASY!!

: A little while back, I was browsing through the newsgroups, just like
you are now
and came across an article similar to this that said you could make
thousands
dollars within weeks with only an initial investment of $6.00! So I
thought,
"Yeah, right, this must be a scam", but like most of us, I was curious,
so I
kept reading.

: Anyway, it said that you send $1.00 to each of the 6 names and
addresses
stated in the article. You then place your own name and address in the
bottom of the list at #6, and post the article in at least 200
newsgroup. (There
are thousands) No catch, that was it. So after thinking it over, and
talking to
few people first, I thought about trying it. I figured what have I got
to lose
except 6 stamps and $6.00, right? Like most of us I was a little
skeptical and a
little worried about the legal aspects of it

: All, So I checked it out with the U.S. Post Office (1-800-725-2161)
and
they confirmed that it is indeed legal! Then I invested the measly
$6.00. Well
GUESS WHAT!!?. Within 7 days, I started getting money in the mail! I
was
shocked! I figured it would end soon, but the money just kept coming
in. In

my first week, I made about $25.00. By the end second week I had made a total over $1,000.00! In the third week I had over $10,000.00 and it's still
growing. This is now my fourth week and I have made a total of just over
$42,000.00 and it's still coming in rapidly.
Its

: Certainly worth $6.00, and 6 stamps, I have spent more than that on the
lottery!!

: Let me tell you how this works and most importantly, why it works?.also,
make sure you print a copy of this article NOW, so you can get the information off of it as you need it.

STEP 1: Get 6 separate pieces of
paper and write the following on each piece of
paper "PLEASE PUT ME ON YOUR MAILING
LIST."

Now get 6 US $1.00 bills and place ONE inside EACH
of the 6 pieces of paper so the bill
will not be seen through the envelope to prevent
thievery.

Next, place one paper in each of the 6
envelopes and seal them. You should now have 6 sealed
envelopes, each with a piece of paper
stating the above phrase, your name and address, and a
$1.00 bill. What you are doing is creating
a service by this. THIS IS ABSOLUTELY LEGAL! This program remains
successful because of the honesty and integrity of the
participants. Please
continue its success by carefully adhering to the
instructions. You will now become
part of the Mail Order business. Your product is simply a
service of helping
develop mail lists. Mail the 6 envelopes to the following
addresses:

#1) Chuck Robertson 2262 Jamestown Ln. Carrollton,TX zip 75006

#2) Lenny Viner 1 milestone Rd. Rye Brook NY 10573

#3) G. Koenig 15558 Old Newport Ave. Baton Rouge,La. 70817

#4) Rudy Mahoney 597 Cote St. Antoine Montreal, Quebec H3Y 2K5

#5) Michelle Dunn PO Box 221 Williamson, Ga 30292

#6) Gayle Failing 924 east tinkham av # 206, ludington, mi 49431

STEP 2: Now take the #1 name off the list that you see above, move the other
names up (6 becomes 5, 5 becomes 4, etc?.) and add YOUR Name as
number 6 on the list.

STEP 3: Change anything you need to, but try to keep
this article as close to original as possible. Now, post your amended article to
at least 200 newsgroups, message board. (I think there are close to 24,000
groups) All you need is 200, but remember, the more you post, the more
money you make

!---- DIRECTIONS----HOW TO POST TO
NEWSGROUPS, MESSAGE BOARD----------

Step 1) You do not
need to re-type this entire letter to do your own posting. Simply put your
cursor at the beginning of this letter and drag your
Cursor to the bottom of this document, and select 'copy' from the edit
menu. This will copy the entire letter into the computer memory.

Step 2)
Open a blank 'notepad' file and place your cursor at the top of the
blank page.
>From the 'edit' menu select 'paste'. This will paste a copy of the letter into
notepad so that you can add your name to the list.

Step 3) save your new
notepad file as a .txt file. If you want to do your postings in different sittings,
you'll always have this file to go back to.

Step 4) Use Netscape or Internet explorer and try searching for various
newsgroups (on-line forums, message boards, chat sites, discussions.) Just
example you log on any search engine like
yahoo.com,google.com,altavista.com,excite.com then you search with this
subject ?millionaire message board? or ?money making message board? or
?employment message board? or ?money making discussions? or ?money
making forum? or ?business message board? etc. You will find thousands &
thousands of message boards. Click one by one then you will find the option
post a new message. :

Step 5) Visit these message boards and post this article as a
new message by highlighting the text of this letter and selecting paste from
the edit menu. Fill in the Subject, this will be the header that
everyone sees as

they scroll through the list of postings in a particular group, click
the post
message button. You're done with your first one!.

: Congratulations? THAT'S IT! All you have to do is jump to different
newsgroups and post away, after you get the hang of it, and it will
take about
30 seconds for each newsgroup! ** REMEMBER, THE MORE
NEWSGROUPS OR MESSAGE BOARD YOU POST IN, THE MORE
MONEY YOU WILL
MAKE!! BUT YOU HAVE TO POST A MINIMUM OF 200** That's it!
You will begin receiving money from around the world within days! You
may
eventually can rent a P.O. Box due to the large amount of mail you will
receive. If you wish to stay anonymous, you can invent a name to use,
as long
as the postman will deliver it. **JUST MAKE SURE ALL THE
ADDRESSES ARE CORRECT. **

: Now the WHY part: Out of 200 postings, say I receive only 5 replies
(a very
low example). So then I Made $5.00 with my name at #6 on the letter.
Now,
each of the 5 persons who just sent me $1.00 make the MINIMUM 200
postings, each with my name at #5 and only 5 persons respond to each of
the
original 5, that is another $25.00 for me, now those 25 each make 200
MINIMUM posts with my name at #4 and only 5 replies each, I will bring
in
an additional :$125.00! Now, those 125 persons turn around and post the
MINIMUM 200 with my name at #3 and only receive 5 replies each, I will
make an additional $625.00! OK, now here is the fun part, each of those
625
persons post a MINIMUM 200 letters with my name at #2 and they only
receive 5 replies, that just made me $3,125.00!!! Those 3,125 persons
will all
deliver this message to 200 newsgroups with my name at #1 and if still
5
persons per 200 newsgroups react I will receive $15,625.00! With an
original
investment of only $6.00! AMAZING! When your name is no longer on the
list, you just take latest posting in the newsgroups, and send out
another
$6.00 to names on the list, putting your name at number 6 again. And
start
posting again. The thing to remember is, do you realize that thousands
of
people all over the world are joining the internet and reading these
articles
everyday, JUST LIKE YOU are now!! So can you afford $6.. and see if it
really works?? I think so? People have said, 'what if the plan is

played out and
no one sends you: the money? So what are the chances of that happening
when there are tons of new honest users and new honest people who are
joining the internet and newsgroups everyday and are willing to give it
a try?
Estimates are at 20,000 to 50,000 new users, every day, with thousands
of
those joining the actual Internet. Remember, play FAIRLY and HONESTLY
and this will work.

Just to bring back to the original discussion and reiterate:

S22 is a small signal (linear) parameter, by definition. It does not apply to the large signal environment.

This idea is somewhat related to the idea that power amps should be tuned for "maximum transfer of power," which is a small signal (s-param) issue, and requires conjugate matching. The idea is incorrect because it ignores the practical large signal non-linearity and *any* consideration of DC to RF efficiency (which is prime for PA design). Linear parameters provide *no* recognition of things like DC to signal power efficiency and therefore practical issues like supply rails.

First order matching of an RF PA to a load involves transforming the load to the optimum point on the AC load line (for example, more or less equal positive and negative swing limits for class A). That's what "matching" is for an RF PA. It makes no statement about actual "output impedance" of the source. What is said is that "such and such RF PA will deliver X power into some specifed impedance within some VSWR circle." That's all. The concept of output impedance begins to break down for large signal devices.

> explanation.

Nice. Exactly: "what it wants to see" is perfect. Of course, "varying the load" requires load pull test equipment and that can be expensive. When load pull equipment is not available, we're stuck with other methodology. In that case, my first order cut is the AC load line, a harmonic short at the device, and enough flexibility in the layout to pull it in by cut and try. I haven't used ADS or Microwave Office's Harmonic Balance simulators. I suppose with good behavioral models and a good simulator, a good deal of cut and try could be circumvented.

Obviously people don't have 100 W (or more!) network analyzers looking into the output and pretending the device is similar to a linear small signal device.

Don't know. Whatever mismatch there is, at whatever moment in time, it simply results in reflection back towards the load. Reflections could also cause additional non-linearity in the PA. Therefore reflections for higher powered PA's are directed off to a dummy load via a circulator.

Thevenin's is a linear theorem. Large signal devices are not linear. (Hey, maybe triodes are, but I don't use them for PA's.)

There is no armchair philosophy about Thevenin's theorem because it does not apply in the RF PA situation. Your's is a red herring.

3121. Re: EZNEC Model of a Tilted Half Rhombic Antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2005-02-28 23:17:54 UTC
From: "William M. Bickley" <bickley@dmv.com>
Message-ID: <11279l2iql5bp8e@corp.supernews.com>
Source record: 81310

For anyone who's curious, the antenna is described as follows:
The tilted half-rhombic antenna resembles the more familiar "sloping V" antenna. The difference is that the tilted half rhombic is fed at an end, and a sloping V is fed at the center (apex). The feedpoint and terminating point of the antenna are placed on diagonally opposite corners of the given area. To keep the supporting structure from being an obstruction, it is located in one of the remaining corners.

From a bird's eye view, the footprint of the antenna is a letter "L", with the apex at the junction of the two legs. The antenna has 27.2 meters of wire in each leg. The included angle formed by the two legs is 95 degrees. The height at the apex is 9.5 meters. A 9:1 transformer is located at the feed end. A 9:1 transformer is attached at the terminating end, to which is attached a 50 ohm dummy load. a counterpoise wire runs between the two transformers, and runs "along or just a few inches below ground."

The gain and SWR numbers included in the article (using AO) are:

Freq Gain (dBi) SWR

28.0 7.5 1.94

24.9 7.1 1.72

21.0 7.0 1.46

18.1 6.0 1.26

14.0 4.0 1.60

10.1 1.7 1.34

How do you arrive at that? FCC rules don't specify the nature of the
music programming, really. If the "music" always has the modulation index
at least 30% with rap, the dynamic range actually needed is much less than
for something from BareNakedLadys

Hi there,
I looked at the 6-BTV as a possibility, doesn't do 12M but otherwise
looks interesting, also requires radials which the MFJ does not...looks
like you do blues music too, I play a little harp *smile*, or used to.

>Obviously people don't have 100 W (or more!) network analyzers looking into the
>output and pretending the device is similar to a linear small signal device.

Hi OM,

Well, it is more accurate to say that you don't, that is for sure.
Defining a solution by negative results can fill up a library without
any positive accomplishment. Obviously people don't have a nuclear
reactor, or lunar lander, or bank account to balance the national
debt. The joke of this, of course, is that no one needs a 100 W (or
more!) network analyzer, or nuclear reactor, or lunar lander, or bank
account to balance the national debt to explain a rather more trivial
problem. Which, by the way, has nothing to do with pretending at all.

The suggestion that
> requires load pull test equipment and that can be expensive
does not negate its existence which commonly proves what you choose to
dismiss as impossible. I have calibrated this gear (called an
artificial or active load), and the gear (called transmitters) it
tests and there are no differences in Physics based upon your
presumption of low-power/high-power demarcations.

To say
>pretending the device is similar to a linear small signal device
is one of those assumptions forced into the argument. There are any
number of ways to do something wrong. Trumping none of these straw
men validates another wrong impression passing as theory. This
returns us to the imposition of impossibilities to answer a rather
mundane concept, eg.
>pretending the device is similar to a small nuclear device
>pretending the device is similar to a mars rover
>pretending the device is similar to the national debt of Lithuania

So to return to a common question that seems to defy 2 out of 3
analysis (and many demurred along the way) - A simple test of a
practical situation with a practical Amateur grade transistor model
100W transmitter commonly available for more than 20-30 years now:
1. Presuming CW mode into a "matched load" (any definition will do);
2. Report the DC power consumed before hitting the key;
3. Report the DC power consumed while holding the key.

Concurrently note:
A. Report Heat Sink Temperature for a previously idle/rcv condition;

B. Report Heat Sink Temperature after 10 minute key-down.

For a hypothetical "100W" model (again, a contemporary, common example for Amateur use) available through standard commercial venues:
2. About 20W - 30W
3. About 200W - 250W
A. About 20 degrees C (or room temperature)
B. Well above 37 degrees C (or skin temperature)

Now, if we are to be any judge of efficiency (Thevenin does not have to be invoked, condemned, or venerated); then it runs close to 50% (ï¿½10%). Others can invoke their favorite deity to explain.

Now, if we are to be any judge of dissipation (no requirement for advanced degree); then heat as a loss by virtue of less than 100% efficiency is quite evident. Others can invoke photons to describe why.

To forestall any armchair engineers, yes, this efficiency is System efficiency. However, I would be surprised if a practical common Amateur grade transistor model transmitter commonly available for more than 20-30 years now has any configuration that does not apply supply voltage directly to the final transistors; and instead adds a significant current path outside of this load (citations to available schematics would be compelling, but any argument without this would be speculation). It takes very little effort to subtract out the power drain of the receive mode (being very representative of the similar power demand of supporting circuitry for transmit up to the driver stage). Barring such amazing evidence of a significant power drain not found in the finals, it follows that a simple computation of efficiency has its merit and has been met.

While I am still digesting this a bit, I at least understand why I was
so confused about the ground loop in the first place. This also
explains why some contradict each other.

As for trying to reach the service entrance here, it is almost not
practical to do so with the antenna elements. The Service entrance
here is kitty-cornered from both the shack and the direction of the
antennas. The antennas would have an extra 150 + feet to feed to go
directly to the service entrance. (dipoles only, no verticals at this
time).

The more I re-read what you said, the more I think I understand. I am in the process of planning a move so I am not planning to improve conditions here but at least I know how to plan for the new QTH.

My battery charger is double fused (positive and negative leads) so I would assume that if lightning tried to find its way to the ground side, it would blow the fuses first. Of course, if it takes 10,000 volts to jump approximately one inch and lightning is typically hundreds or thousands of feet high.... little good the fuse would be in a direct hit.

One of my plans for my next QTH will be to mount feed-through SO-239s on an metal plate and connect my lightning arresters and ground them before the antennas come into the shack. Based on your message, I am thinking that a good connection from there to the service panel ground would be good too?

Thanks again,

Yes Buck, it would be good. Real good ;-)

Even if you add a 120/240v service branch panel to your new shack (as I did), NEC prohibits a separate neutral/ground bonding at that panel. For our purposes, it could be argued that we would be much safer if we could do that, and then let that ground share with the station single point ground. But if you ever had a fire for any reason the insurance would distance themselves from you fast when they saw that. Better to stay code and suffer the (cost) consequences of making the bond to the main service entrance.

RH> requires 1/2 the d-c input to the stage. As this power exits the
RH> stage, it cools as the remaining dissipation is only 1/2 the no-signal
RH> dissipation.

I'm sorry but it is an erroneous conclusion to think it cools. Don't
you recall mentioning that the "average" voltage and current remains
the same? On the contrary, the stage would generate a little more heat
due to the a.c. losses incurred from a small, but non-negligible,
amount of internal resistance. That is because this internal loss
behaves just like a small resistance in series with the source of emf.

RH> An amplifier can be a linear source without operating under Class A
RH> conditions.

I would really find it instructive if you finished up replying to this
message with an example of a "linear" source not operating in Class A?

Hi All:

I currently have a magnetic mount Cobra 1000 antennae on my Suburban, and am considering a switch to some type of hidden antennae, which I have seen somewhere long ago. Most of my CB use is on trips where I caravan with someone, and so performance is not the most important issue.

Do any of you have a recommendation of where/what/how a hidden antenna works and what it's like?

Thanks!

It is in the sense that it improves the source match by trying to hold
the forward power constant regardless of load. Most SWR foldback
systems overreact but a good ALC system, what we called a "leveling
loop" in waveguide reflectometers back in the mid-20th century
certainly improve the source match.

It will take a lot of thrust, that 5-BTV might require 2 propane tanks ;-)
Be sure to disconnect the radials first!

Sorry, couldn't resist that.

3135. Connecting external antenna to a GMRS radio

Newsgroup: rec.radio.amateur.antenna
Date: 2005-03-01 04:55:25 UTC
From: Bababooey
Message-ID: <cb44f230d856c0e5ca7f677377e3a9e4@localhost.talkaboutradio.com>
Source record: 81323

I'm a "newbie" here, and would like to ask for your help with a project I'm working on for school.
I have a GMRS radio with an built-in antenna, and just for experimentation I wanted to see how my coverage would be with an external antenna (I do have a GMRS licence from the FCC). The integrated antenna which is on this radio simply connects to the PC board of the radio when you screw the outter shell of the radio together. I have a 1/4 wave ground plane antenna tuned to the proper GMRS frequency, and I'd like to connect it to this radio, but my question is this...When connecting an external antenna, I will connect the inner wire from the coax to the circuit board where the radio's original antenna was attached. However, I'm not certain where the outter shield of the coax should be connected..To the - side of the battery connection in this GMRS radio? Should there be some kind of capacitor between the inner wire and outter shield of the coax?
I'm only connecting this external antenna long enough to take some measurements I need for this research project for school, then will return it to normal. This isn't a long term illegal modification I'm asking you to help me with, etc.
Thanks for your help!

Being GMRS your radio follows different regulations from FRS radios,
however since the radios you are working with have attached antennas I
would assume that the type acceptance is predicated on only using the
attached antennas. If you remove these antennas and attach an external
antenna you will be in violation of the registration. Momentary
modification or not your base action will be illegal.

If you do do the mod attach the shield to the foil that goes around the
perimeter of the pc board. That is usually a ground. Check the negative
lead (black) from the battery connector. It should connect to this foil
somewhere.

Fuzzball,

I've used this one from JC Whitney with some success (paste this string into your browser)....

http://www.jcwhitney.com/autoparts/Product/showCustom-0/Pr-p_Product.CATENTRY_ID:2001459/c-10101/Nty-1/p-2001459/Ntx-mode+matchallpartial/N-10101/tf-Browse/sct-body/s-10101/th-StoreCatalogDisplay/Ntk-AllTextSearchGroup/ss-10101?Ntt=antenna

This antenna costs under $5, and from what I remember, reception was decent. Basically you unplug your vehicle's AM/FM antenna from the radio and plug it into this small box from JC Whitney. They you use the enclosed cables to connect from the box to your AM/FM radio and to your CB. There are 2 different SWR adjustments on this small box...1 is for your AM/FM radio (if I remember correctly, you tune to a distant station and turn the adjustment until the station is most clear) and then you tune your CB to a certain channel, and this box has a built-in LED that you use to make the proper adjustments to the SWR so your CB reception is good. From what I remember, it worked well, and for under $5, you can't go wrong!

Hope this helps.

wind a small RX i.e.: a field strength coil and LED indicator, or buy one of them cheap 'bug detectors', stick on a gas filled WX balloon, get a hand held radio or mobile phone, and place a RX next to the radio Mic, put your radio on VOX and key from out side, by talking into the hand held, drag the balloon round with long a string observing the bug detector as a led field strength meter by viewing the LED barographs twinkling light, with a binocular. Easier at night.

Asimov wrote:
"I`m sorry but it is an erroneous conclusion to think it cools (when signal exits)."

The Class A amplifier gets all its power from the d-c supply and it is constant, signal or no signal. With signal power output, some of the power in exits to the load.

I`ll use Cecil, W5DXP`s argument. Energy must be conserved. Energy in equals energy out. If some goes to a load it does not stay within the amplifier to make feat.

Asimov also wrote:
"---linear source not operating Class A?"

I`ll give an example. The Class B amplifier is biased near current cut-off. Current is near zero when the signal is. Yet, output can favorably vie with that from a Class A amplifier for purity. I learned that nearly 60 years ago when I built my first 6N7 phonograph amplifier.

Best regards, Richard Harrison, KB5WZI

Hi OM,

One of those Class A characteristics. It is revealed by the rather
more simple solution to the difficult problem I offered:
What is power in?
What is power out?

This characteristic is part of the lore for those who built their own
equipment as one of several NEVERs
Don't let your amp run without drive;
Don't let your amp run without bias.
Both conditions can lead to melt down.

Unfortunately this kind of Ham memory is fading to the point where
many who witnessed this "internal resistance" are not here to point
out the obvious errors in understanding exhibited by the credit card
generation who build their rigs with plastic.

This is why the load must be matched to the amp. Anyone who has fried a
final will tell you so.
Been there, Done that, Got the bottles to prove it.

You entirely missed the point. You don't know the output impedance because you don't have a way of determining it by swinging the output full-scale. Even for class A, large signals will/can have rail to rail swing. The device will not be linear for large swings: sinusoidal input swing will not result in a sinusoidal output swing. But "impedance" is a sinusoidal (s-domain) concept. So how can you define an impedance--a sinusoidal concept--when the waveform is not sinusoidal for an inputted sine wave? The point is that the output impedance is time dependent ("causes" the non-sinusoid output for sinusoid drive), which rather makes the concept questionable. As I wrote earlier, one might decide to consider a time averaged impedance, but I'm not clear on what the utility would be.

There is no "presumption." Linear parameters and theorems totally ignore practical limitations--this is a fact and you can look it up in just about any text on circuit analysis. The simple linear model is perfectly okay for small signal devices. It isn't okay for large signal devices. In any case, load pull equipment does not make the pretense of defining output impedance of an active large signal device. It does say what the load needs to be to acquire maximum

power out of the device.

> To say
> >pretending the device is similar to a linear small signal device
> is one of those assumptions forced into the argument.

No, it isn't. Thevenins and conjugate matching (for maximum power transfer) are explicitly linear small signal device models. Their use in RF PA output design is a misapplication.

> There are any
> number of ways to do something wrong.

We're talking about one of them. Misapplying small signal linear parameters to the output of a large signal device.

Any definition won't do, and for this discussion the specific "won't do" is using conjugate matching which is a small signal (linear) model.

> 2. Report the DC power consumed before hitting the key;
> 3. Report the DC power consumed while holding the key.

Hey, at least you're recognizing that DC power is important. Where in conjugate matching ideas or Thevenins theorem do you see any concern of DC power? That's right, you don't because they a simple small signal models where DC power and voltage have no bearing because the signals are so small, relatively speaking.

You brought up Thevenins and armchair philosophy regarding it, not me. I said Thevenins was irrelevent, and now you appear to agree with me. Ken effectively brought up conjugate matching, not me. The original comment I was challenging was:

"...the antenna works as an impedance mathcing network that matches the output stages impedance to the radiation resistance."

I simply wanted to make it clear that the "matching" done was not an issue of "output impedance" per se. It is an issue of how the transistor is to be loaded to extract maximum ouput power.

Exactly. It is about DC to RF efficiency, as I've been pointing out since my first post, and which you initially commented was "nonsense" but now seem to agree with. "Impedance matching" meant in the normal sense of conjugate matching for maximum transfer of power is a misapplied small signal concept/model. I think that is all I've really been saying.

Realising its not what you are after..

- You live in very flat country? Be careful of high gain if you have hills.

- Dont use directive antennas on the mobile (eg a quad/yagi) as most
comms on VHF/UHF happen by reflection once you are beyond LOS and in clutter

- Height above ground clutter is VERY important. Whatever you end up
purchasing see if you can put it on a very high mount. (Even to the
point of mounting a 6ft poll on the vehicle and the antenna on top of
that - you did say length wasnt important!)

Cheers Bob VK2YQA

Source record: 81340

The most simple way to describe it is -

With a class-A amplifier the power taken from the DC supply remains constant regardless of signal power output.

The device(s) internal dissipation decreases by the same amount as the signal power output (drive level) increases.

If there's any change in power taken from the DC supply as the power output changes then the device is not operating under class-A distortion-less conditions.

KISS. KISS. KISS. KISS.

To slightly change the subject, anybody who mentions a conjugate match doesn't know what he's waffling about.

And if I remember correctly, a 6N7, a class-B dual-triode, metal tube was specially designed to have a very high Mu and could be operated under very simple zero-bias conditions. Each of the two triodes handled one half of the complete audio sinewave.

With grids in push-pull and the anodes in parallel, you could get 10 watts out of it as an HF frequency doubler.

But it would still take the skin off your fingers.

Ahhh! Happy days!

Punchinello.

Hi OM,

And so it remains with additional elaborations not quoted here.

>but now seem to agree with.

Seeming is a rather insubstantial thing to hang your theories on.

>"Impedance matching" meant in the normal sense of conjugate
>matching for maximum transfer of power

And this reveals the error of "Seeming" because the so-called meaning
you ascribe is this same nonsense. Pay more attention to reading
instead of writing. It has been pointed out more than once, and by
several, that Matching comes under many headings. The most frequent
violation is the mixing of concepts and specifications (your text is
littered with such clashes).

> is a misapplied small signal
>concept/model. I think that is all I've really been saying.

And I preserved this clash quoted above as an example. If there is
any misapplication, you brought it to the table with this forced
presumption. The misapplication of S parameters to a large signal
amplifier is one thing, to project this error backwards into the
fictive theory that there is some difference between large and small
signal BEHAVIOR (not modeling) is tailoring the argument to suit a
poorly framed thesis.

None of your dissertation reveals any practical substantiation, hence
it falls into the realm of armchair theory. We get plenty of that
embroidered with photonic wave theory that is far more amusing.

I am trying to gain a better understanding of the issues associated with lightning and grounding, particularly for an amateur radio station. I would greatly appreciate any answers to my questions, given below.

1.) It seems like lightning "finds" a path before actually discharging through it. Is this correct? How fast is the process of finding the path?

2.) Does lightning discharge over one path or many paths? In other words, if lightning strikes a point, and there are two paths from that point to ground, is the energy shared - like a current divider? One would think that this is what happens, with the sharing based upon relative impedances to ground.

3.) This talk about "single point ground" can be confusing, especially when the solution involves multiple ground rods. I believe we are really saying that the station (equipment) should be connected to ground at only one point - but you can have any number of ground connections (i.e., like ground rods) otherwise.

4.) Does the size of an antenna affect the probability of its being struck by lightning, all else being equal? What is the governing relationship?

5.) Finally, consider an amateur antenna on a pole, located some distance from the service entrance of the house. Let's say there is a copper cold water pipe right at the service entrance. Is it wise to place a lightning rod (or rods) right under the antenna, place an arrestor on the coax there and then another arrestor where the coax enters at the service entrance? Is a ground wire needed between the remote ground rod and the cold water pipe?

Thanks in advance,

-JJ

I have 5 minutes before supper to answer this, so it is an off-the-cuff answer which you can look up in greater and possibly more accurate detail later:

For several minutes before a thunderstorm arrives, it pushes a massive wavefront of positive ions over the surface of the earth. This ion "wave" saturates all objects and they begin to emit positive-charged "streamers" skyward toward the thunderstorm cloud. Every object with these positive ions (rocks, buildings, trees, human heads, etc) allows these streamers. Minutes (or seconds) later, a stepped-leader from a cloud will start earthward and the attraction to several of those streamers will grow. Hair could stand up on your neck when this happens. Seconds or parts of a second later, a step-leader will launch from the most favorable of those upward-flowing positive-ion streamers, and the stepped leader will connect to it. A small visible explosion is seen and heard about 150' above ground as this happens (film shows this) and the cloud opens a channel of current to that stepped leader. Milliseconds later a RETURN SROKE from the ground to the cloud opens that stepped leader path wide open, and another pusle or two or three may occur from cloud to ground following that. Lightning has "struck".

Yes multiple paths are likely in most strikes. Current division occurs even through air, we call it voltage division when more than one branch connects with earth, as the current flowing (10-50ka) will be divided according to the varying voltage potentials felt at various points. Voltage division is a good thing when it is where we want it to be. Current then flows on conductors of our choosing!

That's correct. Ideally there would only be one single point ground for an entire structure. But when radio room and AC service entrance grounds are far apart, we bnd them and connect all forms of grounding systems along the way.

>
> 4.) Does the size of an antenna affect the probability of its being
> struck by lightning, all else being equal? What is the governing
> relationship?

No, but the HEIGHT above ground does. Any object that a rolling ball 300' in diameter would touch as it was "rolled" over your property, is an object that is most likely to be struck if lightning occurs in that general area. Lightning can sideflash horizontally for hundreds of feet, and even change direction more drastically, but the rolling ball defines most likely attachment points for a strike.

A "Lighttning Rod" is a roof top or other high fastened "collector" of lightning. The modern name for this is an "Air Terminal". From a lightning rod, bonded "Down Conductors" carry the lightning energy to a "Grounding Electrode" (Ground Rod).

A tower is already a lightning "air terminal" and all it needs is a good ground system to divide the vltage and curent in as wide an area as possible. Even the coax shield must be grounded many times along the height of the tower, and an arrestor (or surge protection device) could be attached at the base of the tower also. Yes it would also be used (as is shield grounding) at the entrance to the structure.

Cold water pipes may be bonded as additional voltage division in a lightning protection ground system, but they are only the source of primary single point ground IF the structure's AC service entrance uses them as such.

Lets start by first adjusting the perspective. CG lightning seeks charges located 5 kilometers over there. Therefore the shortest electrical path is 3 kilometers directly down to tree, antenna, or utility wire. Then 4 kilometers through earth to those charges. Where will lightning strike earth? Answer is better found in geology. What is the more conductive earth? Has a transcontinental pipeline changed the electrical nature of that region? Obviously the answer is not always obvious. Then many assume lightning is capricious.

Some campers slept near a tree when that tree was struck. Those sleeping tangential to the tree were not affected. Those sleeping pointed at the tree required medical treatment. An electrical path was down tree, through earth, up into human body at the feet, out of human body at the head, then onwards to earth borne charges located elsewhere.

IOW, the camper who required medical treatment were, in essence, earthed at two separate points (at foot and head).

Suppose we had surrounded the camper with a buried electric wire loop. IOW the conductive path was around the sleeping camper. A single point ground (equipotential) was created beneath the camper.

Single point ground can be a single earth ground rod at one of the building, or it can be accomplished by making earth beneath equipotential. But it comes back to a basic concept. No current flows if an incoming and outgoing path does not exist. Goes right back to elementary school science that defined electricity. First a complete circuit must exist meaning that each component must have both an incoming and outgoing path.

The concept of single point ground is make only one connection so that both incoming and outgoing paths do not exist. Some examples of how this is accomplished:
http://www.erico.com/public/library/fep/technotes/tncr002.pdf
http://www.cinergy.com/surge/ttip08.htm

http://lists.contesting.com/archives/html/Towertalk/2002-09/msg00644.html
http://lists.contesting.com/_towertalk/1997-April/004413.html
http://www.leminstruments.com/pdf/LEGP.pdf (see page 14)

How multiple earth grounds can cause damage to a fax:
http://www.epri-peac.com/tutorials/sol01tut.html

Notice even a buried wire can carry destructive transients
as demonstrated by the phone wire in that erico.com figure.
Even a buried wire must connect to the single point earth
before entering a building so that all wires enter at the
single point:

no, it takes all the possible 'paths' at once. ones that end in high
impedances reflect most of the current back and then it goes down some other
path... ones that end in low impedances suck more current out of the system.

>
> 2.) Does lightning discharge over one path or many paths? In other

yes, as above... it goes down all paths and ends up sharing them based on
relative impedance exactly like a current divider but with time delays based
on the lengths of the paths and terminating impedance.

>
> 3.) This talk about "single point ground" can be confusing, especially

yeah, thats a reasonable way to look at it. it kind of looks like an
hourglass with everything being connected at one common point and spreading
out in the shack on one side and into the ground on the other side but
possibly with multiple connections on both sides.

>
> 4.) Does the size of an antenna affect the probability of its being

the bigger it is the more likely it is to get hit.

>
> 5.) Finally, consider an amateur antenna on a pole, located some

> remote ground rod and the cold water pipe?

this is actually a couple (relatively) unrelated questions.

the more rods the merrier. the more paths you can give lightning the less of it will get into your shack. just don't put the rods too close together or you are wasting money, put them at least their own length apart from each other and connect by heavy wire, cadwelded, etc, etc.

yes, you can put arresters at each end of a cable, but its probably only worth it if the cable is relatively long... on a swag i would say if its shorter than 100' its probably not worth two arresters, just put one at the service entrance. the function of an 'arrester' is to just equalize the voltage between the shield and center conductor and since the critical point for that difference is at the radio end that one is more important.

i believe code requires water pipes to be connected to the service entrance ground. the service entrance ground should also be connected to the ground at the antenna, so indirectly the water pipe and remote rod would be connected.

Logic says no. As a charge starts to build, it also starts to flow. If the discharge path has high enough resistance, it wont flow until the charge reaches a certain potential. That may be what you were trying to ask. Then we are speaking of a dielectric. When the potential becomes large enough to punch through the dielectric, then the discharge occurs.
>
> 2.) Does lightning discharge over one path or many paths? In other

No need to make lightening too mysterious. It is electricity, and if there are two solid paths of basically equal resistant, it will flow in both. It is important to note that I did say basically EQUAL. Two paths may be equal at low voltages, but at high voltages, in bends of wire, the lightening has been known to burn off one path.
>

I cant tell you much about this. Its safer for the equipment to have only one ground connection as the surge caused by lightening can enter from any of the grounds if its not a direct hit to the antenna itself.
>
> 4.) Does the size of an antenna affect the probability of its being
> struck by lightning, all else being equal? What is the governing
> relationship?

Again, logic dictates that a bigger antenna can be closer to a charged area than a small one. That being said, it probably doesnt make much difference

unless youre running some very longwire type of antennas. A yagi or a quad
will probably not change the chance of getting a hit very much.

Don't connect it to your water pipe. That's a good way to get a damaged
water pipe if you take a hit. Use grounding at the antenna support. You CAN
use arrestors, but the way our hardline at work is grounded, they just trim
off the outer jacket and connect a clamp for grounding, then cover it with
weatherproof putty. They are grounded at the base of the antenna tower, then
at the point of entry to the cellsite. Then there is a ring ground inside
the cellsite, and that ring ground is connected to a groundrod outside the
site at the opposite corner from where the antenna feedlines enter. Cant
explain how it works all that well, but we seldom have much lightening
damage to our equipment, and its directly connected all the time. We do use
surge protection to protect the power wiring to the equipment as well. There
are probably others on here that can give you more info than I can. There
are also standards that are set up by NEC that need to be followed as well,
if I'm not mistaken.

Oh and as a caveat, this is only my opinion from what I have studied and
seen. It is by no means advice as to what you should do in your case. NEC
are the ones that set the standards and inspectors are probably the best
ones to tell you what has to be done.

Right. 5 elements on 2 meters, 5 on 440.

>Probably not easy to use mobile (portable, maybe).

True... but the original posting made a point of asking for maximum
gain, and said that type and mounting weren't important. Nothing was
said about "omnidirectional" one way or the other. (##grin##)

Right, I should bave been more clear, I'm looking for an
omnidirectional vertical.

I once had a Hustler 2-meter collinear, something like 5 db gain
omnidirectional, and five feet tall or thereabouts, with a 3/8x24
mount. Never had a better 2 meter mobile antenna before or since.
But, it only comes in a monoband version, and only 2 meters and 220.
If I could find something dual-band for 2 and 440 that's as good as
that one was, I'd be happy.

Finally Moving back to an area where I can use my rig again. I will be in a two story house and was wondering how running a wire around 2 or 3 sides of the house, under the roof overhang eaves would work. Its actually a "stilt" type or "beach" type house, and the roof eaves are probably 25 feet up. I had a long wire some years ago, and got great results. Would this work well, and should I use 2 or 3 or all 4 sides? Also... Grounding from the 2nd floor.... Is that going to be a problem?? Thanks in advance. Gene K3ASA

Anyone familiar with the Carolina Windom? What is it's claim to fame?
Looks like nothing more than a dipole fed off center with an isolator
to limit feed line radiation.

Any insight will be appreciated.

Best remove that whole paragraph from your lightning vocabulary and pretend you never saw it before. It is completely incorrect and misleading to allude that lack of a path or circuit will protect anything from lightning. The opposite is true.

The bonding of all nearby electrically conductive objects is what makes them equipotential, because current does not flow when there is no potential between bonded equipments. Interrupting the "circuit" by failing to properly bond will allow massive potentials and lightning will find several paths you should have known about and others you never knew possible.

Creating "Equipotential" (bonding) and "Grounding" are two distinctly seperate principles. Both are required in a system of lightning protection. If there was one that was immensely more important than the other, it would be the bonding. A well bonded system "could" survive direct lightning strikes to the structure with no damage to the equipment even if there was never a ground connection made (happens to airplannes frequenty). But no ground system conceivable can allow an equipment room that is not properly bonded to survive a strike. Applying the two principles of bonding and grounding together (and surge protection), is what helps control all the entrance and exit paths for lightning, and makes a lightning protection "system".

A well bonded system means all those other potential
'outgoing' paths are connected to the same 'incoming' path.
IOW bonding converts all other possible electrical paths into
the same, common incoming path. If all circuit paths only
connect to the same 'incoming' path, then there is no outgoing
path necessary to conduct electricity.

This is also why equipotential grounding works. But this is
arguing semantics. Bottom line is the perspective of a
protected circuit. If all incoming paths are properly bonded
to a same point, then no outgoing path exists. No outgoing
path means no destructive electricity flow through that
circuit. Therefore no damage.

If antennas are physically about the same size you are not going to
see a dime's worth of difference between them.

If you happen to look at your S-meter when driving you will note it is
not unusual to see signals varying more that 20 dB as you are diving.
Believe me you will never notice a 1-2 dB difference.

"1.) It seems like lightning "finds" a parh before discharging through it."

Speculation is tempting. I would not swear to a sequence of events but J.J.`s scenario seems plausible.

Lightning breaks down the dielectric of the atmosphere at some point where the potentiaal gradient initiates a huge arc. Charges are accumulating and moving about until an ignition potential is reached at some point.

Influence of accumulations of charges and their movements must be propagated at the speed of light, thought by many to be the final speed limit. Communication of electromagnetic forces among the atmospheric charges may be considered "finding a path" for the lightning bolt.

You don't have to swing the output full-scale to measure the impedance.
Any change in the load, no matter how small, will cause a change in the
output voltage and the output current. From these you can calculate the
output impedance at the current operating point.

When a transistor is operating under large signal conditions into a tuned
load, there is still an output impedance and this impedance still
discribes what will happen for small changes in the load.

J.J. wrote:
"4.) Does the size of an antenna affect the probability of it being struck by lightning?"

Probably. It`s a bigger target, more likely to have some part nearer a highly charged area of the atmosphere. A short distance makes a high gradient. If the antenna has sharp points it is more likely to trigger lightning.

Best regards, Richard Harrison, KB5WZI

J.J. wrote:
"Is it wise to place a lightning rod (or rods) right under the antenna---?"

Yes. It is a good practice to help nature to neutralize its excess charge in the shortest time and distance. The sooner this gigantic force is diluted, the safer everything and everyone is. But, if your outside plant is impervious to damage, you may choose to put your arc gaps and ground rods back at the station ends of your transmission lines.

Actually, the isolator is some number of feet from the
feedpoint which ensures feedline radiation. The Carolina
Windom is a compromise between horizontal and vertical
radiation. It's performance falls between a horizontal
dipole and a 1/4WL vertical. Depending upon who you talk
to, it is either the best of both worlds or the worst of
both worlds.

With the Carolina Windom, the most vertical radiation is found on 160m, where the thing acts like a short, top loaded vertical. The ant is fully bandswitching, and will load on some bands without a tuner. The main drawback is the limitation that applies to all horizontal antennas, and that is height above ground. Most horizontal antennas are substantially cloud warmers at less than 1/2 wavelength height.

Gee I am gong to have to learn those state abbreviations... So many of them start with "M" <grin>

I use to work on UHF radio equipment installs being used on the flat areas in western NSW (Australia). One of the common setups was a 9dB fibreglass whip (476MHz - about 6ft long). It had to be setup just right otherwise the few degrees of tilt you got from air movement would lift the pattern in front of the vehicle above the horizon and make it all but useless.

I also hear that 1/4 wave whips are almost essential if you are driving amongst high rise buildings.

Also did some tests recently on the "gain" of a vehicle mounted 1/4 wave vs a test dipole antenna at 4 metres height. There was about 10dB between them, we assumed because the 1/4 wave was still very much in the ground clutter. This was on 149MHz and LOS.

My view is that any dual band antenna is going to be a huge compromise anyway and high gain on both bands unlikely. I am however prepared to be shot down over this!

Apologies for waffling on!

RH> The Class A amplifier gets all its power from the d-c supply and it is
RH> constant, signal or no signal. With signal power output, some of the
RH> power in exits to the load.

Let's look at it from the dynamic point of view. When there is no
signal the circumstances are as you describe. When the signal swing
turns the device nearly OFF there is a maximum voltage across the
device but the current is a minimum or close to zero.

Conversely when the signal swings in the opposite polarity the device
turns ON hard but the voltage is at a minimum or near zero too. In
either case the "ideal" device dissipates no extra power because the
two products are always zero. In fact the power difference is
always zero, so there is no reason for the device to cool.

However, no device is ideal, it has losses, and generates harmonics.
If the rectification is such that the average current decreases then
the device will cool. There is a gotcha however, because the harmonics
rob power from the desired output.

RH> I`ll use Cecil, W5DXP`s argument. Energy must be conserved. Energy in
RH> equals energy out. If some goes to a load it does not stay within the
RH> amplifier to make feat.

As you said, if the amplifier dissipates 100W when idle and it can
drive 100W into a load then the power source will still supply 100W
when so doing, of course being an ideal device and neglecting all
other losses. It is easy to test by paralleling a substantial
capacitance and measuring the supply current before the cap. The
current should remain the same or rise only very slightly.

RH> Asimov also wrote:
RH> "---linear source not operating Class A?"

This incremental impedance is one of several different impedances that
can be defined for a non-linear source. No one is more valid
conceptually than another, but some are of more practical significance
than others.

The point is that if you want to talk/write about one of these
impedances, you need, to prevent misunderstanding, use a precise term,
such as 'incremental output source impedance' and define it.

I'm using the Comet CA-2x4SR . It seems to work quite well on 70cm
and about the same as 5/8 wave on 2m. I had originally tried a
Jetstream JT7905L and it actually seemed a little better on 2m and
70cm receive, but the swr was higher than I liked on the high end of
70cm where the local repeater inputs are .

Hi OM,

This goes into the intricacies of how forced propositions do not yield
a forceful argument.

On Tue, 01 Mar 2005 18:06:18 GMT, gwhite <gwhite@deadend.com> wrote:

>You don't know the output impedance because you
>don't have a way of determining it by swinging the output full-scale.

This is more properly an admission from you, than a projected
inability upon us. You may not know how, but this does not prevent me
from expressing a value that is suitably accurate.

Now, within the field of measurement, no statement is accurate without
an expression of its range of error. However, in this regard accuracy
is still a remote issue as you offer nothing of practical
consideration and have failed to respond to a simple example to
provide context.

Richard Harrison, , KB5WZI, has in this sense already done the heavy
lifting with:
>>From the specifications page also, the power reguirement is TX: 18A
>>13.8V DC. It`s a linear amplifier. Only 40% efficiency. The designer
>>probably was more interested in low harmonics than efficiency. The final
>>by itself only takes part of the 18A ao its efficiency is more than 40%.

continuing....

>Even for class A, large signals will/can have rail to rail swing.

This marks an artificial imposition not required to respond to the
spirit of the topic. Such swings are not necessary.

>The device will not be
>linear for large swings: sinusoidal input swing will not result in a sinusoidal
>output swing.

This is immaterial to impedance and is a set-up of another artificial
imposition: the Thevenin Model (which was specifically dismissed).
Hence we are into a cascade of impositions.

>But "impedance" is a sinusoidal (s-domain) concept.

This is baloney cut thick. S Domains (?) are at best a modern
contrivance to model well behaved small signal devices. Their utility
follow theory, they do not drive theory.

>So how can
>you define an impedance--a sinusoidal concept--when the waveform is not
>sinusoidal for an inputted sine wave?

There are no sine waves in nature, so by this contortion of logic from
above there are no s-domains (?). Why are there no sine waves in
nature? Because nature is bounded by the Big Bang (a discontinuity)
at one end, and has yet to fulfill its infinite extent.

In other words, tedious appeals to artificial impositions of purity
fail at the gate for their sheer collapse of internal logic. This
kind of stuff appeals to arm-chair theorists who find themselves
impotent to perform.

> The point is that the output impedance is
>time dependent ("causes" the non-sinusoid output for sinusoid drive), which
>rather makes the concept questionable. As I wrote earlier, one might decide to
>consider a time averaged impedance, but I'm not clear on what the utility would
>be.

Classic performance anxiety. Engineers learn to live with limitation
and to express results and sources of error so that others can judge
merit. Priests are better suited with mulling over these issues of
ambiguity.

>There is no "presumption." Linear parameters and theorems totally ignore
>practical limitations--this is a fact and you can look it up in just about any
>text on circuit analysis.

Knowledge limited. There are many suitable texts that offer a wider
spectrum of discussion that are fully capable of answering these
issues. However, it is made worse that most of this stuff is
derivable from first principles and no recourse to vaster libraries is
actually needed.

>The simple linear model is perfectly okay for small
>signal devices. It isn't okay for large signal devices.

And yet there is no substantive illustration to prove this ambiguous
point. What constitutes small, and what demarcates large? Such
nebulous thinking clouds the obvious observation that the full range
of devices themselves operate on only one principle. What is limited
is the human component of their perception, not the physical reality
of their operation. The faulty choice of models (S Parameters) is not
the fault of either Physics or the devices when they diverge from the
crutch of calculation against the wrong mathematical expression.

> In any case, load pull
>equipment does not make the pretense of defining output impedance of an active
>large signal device. It does say what the load needs to be to acquire maximum
>power out of the device.

This is simply the statement from a lack of experience.

>Thevenins and conjugate matching (for maximum power transfer) are
>explicitly linear small signal device models. Their use in RF PA output design
>is a misapplication.

These statements are drawn from thin air.

>> So to return to a common question that seems to defy 2 out of 3
>> analysis (and many demurred along the way) - A simple test of a
>> practical situation with a practical Amateur grade transistor model
>> 100W transmitter commonly available for more than 20-30 years now:
>> 1. Presuming CW mode into a "matched load" (any definition will do);
>
>Any definition won't do, and for this discussion the specific "won't do" is
>using conjugate matching which is a small signal (linear) model.

Given the failure to provide any discussion for either or any form of
matching suggests a lack fluency in any of them.

>*You* brought up Thevenins and armchair philosophy regarding it, not me.

I rejected it as an unnecessary filigree, but I notice in the quotes
above that you readily embraced it as a necessary imposition.

> I said
>Thevenins was irrelevent, and now you appear to agree with me. Ken effectively
>brought up conjugate matching, not me.

This compounded with the denial of Thevenin is quickly closing the
available matching mechanisms. If it is not about Thevenin, and it is
not about Conjugation, then I am willing to wait to hear what it IS
about.

...But not really. I have little faith that the difference is
appreciated nor how many ways a match may be accomplished or for what
ends.

>The original comment I was challenging
>was:
>
>"...the antenna works as an impedance mathcing network that matches the output
>stages impedance to the radiation resistance."

I am always suspicious of how a quoted claim is couched by the
rebutter (cut and paste from the original is always available and
citing the link to the complete contextual post is hardly Herculean).
However, responding to the bald statement, I find nothing
objectionable about it.

>I simply wanted to make it clear that the "matching" done was not an issue of
>"output impedance" per se. It is an issue of how the transistor is to be loaded
>to extract maximum ouput power.

Again, a presumption not brought to the table. It may follow as a
consequence, but it is not a necessary condition.

Our questioner who started this thread is undoubtedly interested in the outcome in terms of maximum radiation for a limited power - it is a chain of causality that is a forced step matching issue from the battery to the ï¿½ther. This is a first principle of successful production engineering.

Here's what I'm doing and I'd like some feedback.

Antenna will be an 88ft doublet 30-40ft high supported at the center by a ladderlock and fed by 450ohm windowline. The windowline will drop down to within 8ft of the ground (above kiddie reach) where it will be connected to a W2DU style choke balun based on RG213 and Palomar BA-8 ferrites. This will be enclosed in a ~12" length of electical conduit which will be supported to relieve the windowline of further strain.

The coax will connect at the bottom of the choke enclosure via PL259/SO239 to a ~10ft length of RG213 down to earth level driploop and up into a small lockable mushroom enclosure containing a ICE300 supported on a 5/8"x8ft copper ground rod. Also contained in the enclosure will be an LDG RT-11 tuner which will be mounted on the backside of the ground rod from the ICE300. A small RG213 jumper will connect the ICE and RT. The shell of the shielded DB-9 control line will have a small braid to bond it to the ground mounting point as well.

The coax and shielded DB-9 control lines from the RT will drop out of the enclosure via PVC conduit to an undergound PVC junction box which has it's bottom side perforated to drain any condensate. The run to the house from this JB is ~50ft with a >1ft rise which should ensure a flow of any condensate to the JB drain. The RG213 will be direct burial grade but I've not been able to find any shielded DB-9 direct burial cable hence the electrical PVC conduit.

At the house end the PVC will sweep up to another small enclosure atop another 5/8"x8ft ground rod holding a grounding point for the shells of the coax and control lines and also will terminate the line from the station bond from inside the shack. The lines will then enter the house through a driploop and travel ~5ft to the shack.

At the shack a ground bus will be provided where each of the pieces of equipment will be bonded individually. This ground bus will be connected via a 3" copper strap 5ft back out to the ground rod at the entrance to the house.

The station ground outside the house is 40ft away from the service entrance and its ground. I'm thinking of running "something" from the station ground rod to the service entrance. I can easily periodically "terminate" this with some intermediate ground rods if necessary along its length.

What should the "something" running between the station and service ground rods be?

How often should any periodic termination rods be added?

Any help on direct burial shielded DB-9 cable?

tnx
jtm

Here's the reason the device cools under load.

Plate loss = Eb*Ib - Ip^2*RL

With no signal, the plate loss is Eb*Ib. When
the signal is increased from zero, any power
delivered to the load is subtracted from Eb*Ib,
thus causing the device to cool.

Cecil is correct. I have had a couple of them and they work well, but do have their limitation. I was able to get up about 75/80 feet in the air and it was very good on 20/18 meters the other bands were okay but nothing to write home about.

Not only that, but since by definition the Universe started at T=0, any
'sine wave' that starts at a positive zero-crossing is at any later time
indistinguishable from a real one that started at T=0.

Assuming you are going to use this system on 20m, EZNEC says
the 10' piece coax will see 166-j960 ohms for an SWR in excess
of 100:1. Depending upon where the voltage antinodes are located
and how much power you are running, that may be enough to cause
arcing at the coax connectors.

Why not run the ladder-line all the way to the tuner? Hint: SGC
says not to tie transmission line to the outputs of their SG-230.

Hi Cecil

Output power for my use will never exceed 100W, more typically 5W or less. The RT-11 is only rated to 125W. But your caution on impedance is just the sort of feedback I was looking for. I was considering running the windowline all the way to the ground but was concerned about the neighbors' kids getting their hands on it. My alternative was to run a bit of conduit upwards to shelter the windowline until it was out of reach, ~8ft. I was concerned however about how large such a PVC conduit would need to be to avoid problems with the windowline. Would 2" be big enough since its non-conducting?

tnx

Jim, if you use twin-lead from choke-to-tuner as Cecil suggested, the coax arrestor model at the tuner can be changed to ICE-304U per http://www.arraysolutions.com/Products/ice/impulse1.html#2

40' is at least 2x too long for a bonding jumper, according to a PE's interpretation of NEC-70/NFPA-780. That leaves up to you what to do to mitigate this problem. Practically speaking, you can not provide a low impedance connection that far no matter what conductor was used. But compared to the home's AC ground wiring which is outrageously high impedance, you can provide reasonable equipotential with the service ground. A minimum of one 8' copper clad ground rod, driven 10' into the ground every 2x rod depth feet is the code requirement for grounding electrodes. Applying that electrode-length requirement to a distance too long for a bonding jumper is not defined in the code, hence the professional opinion that was required in my case, which I share with you. In that similar situation, I used 4' copper ground rods every 8' along the bonding-path to the service entrance. The risk involved with such a long jumper is Ground Potential Rise. This could draw current from the station ground up into the bonded equipment cases, overpowering the withstand design of the equipment, and exiting the equipment via the AC connections and coax feedlines. As long as you provide a bond that is significantly lower impedance than the AC wiring to the service ground, you have minimized GPR-risk. Not eliminated it. The better the bonding and voltage-division your ground system provides (radials, improved service entrance ground, ground rings, ufer-grounds, etc) the more protection from GPR you provide. Your bonding must be capable of balancing the GPR across the entire system. Since the withstand of most equipment is approximately 2,000v, you should not have a problem maintaining a much lower potential than that.

The only other thing I would add, is an ICE-300 on the equipment ground bus-bar, after first shield-grounding the coax feedline at the station single point ground.

Asimov wrote:
"Let`s look at it from the dynamic point of view (loss in a Class A amplifier)."

The no-signal loss of a Class A amplifier is 100%. It equals volts x amps and appears in the amplifier. Now feed a signal to the ideal amplifier set just below the clipping level. Average d-c power is unchanged from the unloaded and no-signal conditions.

Connect a matched load resistor to the amplifier output. If physically small, the resistor may become warm with heat that were it not for the load would be otherwise dissipated in the amplifier. Input power to the Class A amplifier is unchanging.

Finding the internal resistance theoretically is simple. It is simply the open-circuit output voltage divided by the short-circuit current.

Open-circuit voltage at full output and short-circuit current may be severe. Internal resistance can be found under less stressful conditions. Internal resistance will drop the voltage to any load reasistance. Use the voltage-divider formula to calculate the internal resistance.

With pure resistances, half the open-circuit volts are dropped by the internal resistance when the load is a match.

A power amplifier`s internal impedance can be determined.

Power output from a Class A amplifier cools it.

Best regards, Richard Harrison, KB5WZI

Hi Jack

I missed something in the above: you said an 8ft rod driven 10ft into the ground? Does that mean the top of the rod is buried 2ft?

Then driving such a rod every 2x rod depth feet would mean one every 20ft vs every 16ft?

What would be the recommended connecting conductor between all the points? Big honking cable or copper strapping?

I haven't purchased the ICE unit yet until I had gotten some feedback so making that change is no problem.

So you would suggest two ICE units? One at the antenna base and another at the station ground?

BTW, I'm wondering if any installation has ever met the codes you cited other than a dedicated broadcast transmitting facility. Certainly would be the exceptional (<1%) residence in my experience.

thanks for your help!

Source record: 81243

I've got a little shortwave receiver that has a decent amount of gain in it's antenna input. I've been experimenting with different lengths and placements of the wire, and seen some interesting homebrew antennas I might try once the snow melts.

I know that receivers are less demanding of impedance matching in general, but my readings suggest that I should have a balun (unun) of some sort to match the impedance better, since I'm pretty much stuck with end-fed longwires. This should get more signal to my front-end, and a proper shielded connection to my receiver should help minimize stray RF noise.

I'm a renter, so I'm going to experiment with running a wire along the eaves on the balcony, which is open to two sides of the house (wooden two-story.) That is, I do not have the luxury of using the yard, trees or anything.

So, my idea is to have a long wire (or folded longwire made from a length of twin-lead) go to a balun (or unun, since this is really unbalanced-to-unbalanced) and then run a downwire from there to my receiver through a window.

I'm guessing the real advantage would be realized if I had a good RF ground at the receiver and/or balun. This will be sort of tricky. I don't even think I have copper cold-water pipes anywhere, and running copper braid over the balcony, down the side of the building and into 6-foot rod just ain't going to happen. I've heard of people using houseplants for poor grounds when no other was available, and I have many kilos of wet earth on the balcony.

I've seen a neat artificial ground/antenna tuner from MFJ (I think) which seems to offer a lot of bang for the buck. It even has multiple inputs for high-Z single wires. Would this be useful for SW?

Finally, I'm probably just going to wind my own balun out of a ferrite core. I just can't seem to find the details on how to wind the copper. Do I wind the primary first around the whole core, and then the secondary on top of it? Sorry if this is stupid question, but I've got most of the math figured out (i.e., no. of turns and such) but since I've never seen a balun... my assumption (right or wrong) is that it is just a special transformer.

Thanks for your comments.

Hi Jim, I was quoting from the fire and electrical codes regarding grounding electrodes, and yes they mean buried 2' beneath ground surface to reach a total depth of 10'. Use the length of the rod in the ground, not rod depth when determining spacing. That confusing aspect came about when 10' rods were going to be maintained as the minimum length allowed, and contractors screamed they could not obtain them (cheaply). So the 8' rod buried to a depth of 10' was born.

Use 16' as the spacing between buried 8' rods.

Recommend minimum #4 copper or heavier for the service entrance to station bonding connector. It does not have to be continuous if intermittent-spaced ground rods are used. If you figure out some way to efficiently trench for 6" deep >26ga copper strap, please let me know - that would be ideal. Strap is also difficult to bond to ground rods, and generally too thin for exothermal (cadweld) connections.

As for using two coax lightning arrestors, that might rarely if ever be specified. Normally the shield-grounding along the tower and at station entrance is sufficient that one arrestor either on the master ground bus or right outside at the 1st ground rod would suffice. But you are trying to protect your external tuner (let us know how that works out) and might permit some voltages the receiver front-end doesn't like, should they be induced or shorted from shield-to-conductor along the feedline path.

As far as meeting electrical codes and fire standards for grounding systems, there is no way around that in my opinion. If your home is going to be protected from loss by insurance, then you either need to meet all codes and standards, or else somehow demonstrate that you isolate all systems safely before the risk of loss occurs. Personally I don't know how most amateur operators ever collect for lightning damage, since examination by forensic (fire) investigators could show failure to meet code and/or best industry practices in most cases. Yes, you are a "broadcast station" wrt lightning, and in an area subject to it, should take appropriate measures to either always be isolated before the risk occurs, or withstand the risk by plan and design. Proper isolation is not just tossing the feedline out the window as so many unfortunately believe. Considering the risk involved if proper isolation is not followed, protecting the whole property seems like a better plan to me.

LOL. Sure, the purpose of a power amp is to actually extract power. This is a good start.

Perhaps a simplistic (and of course idealized) class A example would help. And I want to remind that this is a simplification of the first order design cut.

The first assumption/idealization for the class A example would be to demarcate between strong and weak non-linearity. This demarcation is basically the boundary of clipping, both positive and negative. That is, we want our class A amp to swing to the rails but not go beyond. In our class A design we will accept weak non-linearity but not strong non-linearity.

Lets say we have selected a class A device/amplifier for which we can statically dissipate 10W. The drain DC circuit is simply an RF choke (see, it is a simple example!). Let's say the quiescent values are a 10 V supply and 1 A of current (10 W). The question is: how do we load the device to extract maximum power given the "no clipping" (strong non-linearity) constraint?

Say we load it with 20 ohms, what happens? The max positive swing before clipping is Id*rL = 1*20 = 20 V. The max negative swing is, of course, Vd = 10 V. Since the 10 V is the lesser of the two swings, our non-clipping design constraint limits us to 20 Vp-p. So we can deliver (Vp)^2/(2*rL) = (10)^2/(2*20) = 2.5 W.

Say we load it with 5 ohms, what happens? The max positive swing before clipping is Id*rL = 1*5 = 5 V. The max negative swing is, of course, Vd = 10 V. Since the 5 V is the lesser of the two swings, our non-clipping design constraint limits us to 10 Vp-p. So we can deliver (Vp)^2/(2*rL) = (5)^2/(2*5) = 2.5 W.

Say we load it with 10 ohms, what happens? The max positive swing before clipping is Id*rL = 1*10 = 10 V. The max negative swing is, of course, Vd = 10 V. Since they are equal, we get 20 V of p-p swing. So we can deliver (Vp)^2/(2*rL) = (10)^2/(2*10) = 5 W.

Our circuit loaded with 10 ohms delivers twice as much power as with the lesser 5 ohms or greater 20 ohms. That is, extracted output power is peaking at some finite non-zero value. This is also easily seen to be most efficient point for this simplistic example.

In no way was the ouput-Z of the amplifier considered in deciding how to load it for the purpose of extracting maximum power from the circuit. The output-R is completely irrelevent.

This example is intended to be illustrative rather than exact.

> The reactive component issue is still there too. Reactive loads cause
> increased currents in the output stage without delivering any power to the
> load so they still need to be reduced as much as practical.

Yes, I already noted that for that portion of the impedance, it should be tuned out *as best* possible.

"...(to be fair, the time-averaged reactive output component is tuned out as best possible)."

Well they are apparently your's too! Your own example of testing your own PA said absolutely zip about output-Z. The most you could say is how the circuit is loaded and its RF/DC efficiency. You're agreeing with me and can't even seem to recognize it.

> >"Impedance matching" meant in the normal sense of conjugate
> >matching for maximum transfer of power
>
> And this reveals the error of "Seeming" because the so-called meaning
> you ascribe is this same nonsense.

Here's the original quote [Ken]:

"When the correct matching is done, the antenna works as an impedance mathcing network that matches the output stages impedance to the radiation resistance."

He brought up "matching to the output impedance" (of the device), not me. There is no "misinterpretation of meaning" when it comes to making statements about matching output impedance to a load impedance. The meaning is well-understood and precise. It means conjugate matching for maximum power transfer, and this is explicitly sourced from small signal theory. Small signal theory is oblivious to practical factors like supply rails and efficiency. These practical factors are paramount in PA design. Thus to apply a theory that ignores paramount factors is to beg a design which will likely be non-optimal.

> Pay more attention to reading
> instead of writing.

I'm paying attention, you agree with me but don't have the background to understand it.

> It has been pointed out more than once, and by
> several, that Matching comes under many headings. The most frequent
> violation is the mixing of concepts and specifications (your text is
> littered with such clashes).

No, you still don't get it. I don't have a problem with saying it is "matched." For example, I said a PA needs to be "load-line matched." This has a specific meaning, and that meaning explicitly isn't "impedanced matched," which means something else. If you don't bother to know what the words mean, I might as well speak Swahili.

> > is a misapplied small signal
> >concept/model. I think that is all I've really been saying.

There is no forced presumption. The words have explicit definitions. If you don't know the language, you have no way of communicating.

> The misapplication of S parameters to a large signal
> amplifier is one thing, to project this error backwards into the
> fictive theory that there is some difference between large and small
> signal BEHAVIOR (not modeling) is tailoring the argument to suit a
> poorly framed thesis.

The models come from behavior and/or device physics, and were developed for the express purpose of efficient design methodology. Small signal models can (and do) conveniently ignore large signal concerns such as efficiency and supply rails, because such concerns are irrelevent in the small signal milieu. To apply a model to a milieu for which the model is not suited begs a non-optimal design. The output-impedance concept itself is quite dubious for large signal amplifiers.

> None of your dissertation reveals any practical substantiation, hence

No one said they "are necessary." But not driving "as hard as possible" simply
means you are wasting power and paying for a bigger device than you need to.

> >The device will not be
> >linear for large swings: sinusoidal input swing will not result in a sinusoidal
> >output swing.
>
> This is immaterial to impedance,...

Oh? The definition of impedance is:

Z = V/I

V and I are sinusoid (phasors), *by definition*. It is as if you don't know the definition of impedance.

> and is a set-up of another artificial
> imposition: the Thevenin Model (which was specifically dismissed).

S-domain *is* linear circuit theory.

> Their utility
> follow theory, they do not drive theory.

It *is* linear circuit theory. The theory was developed for its utility.

http://www.amazon.com/exec/obidos/tg/detail/-/0801869099/

What are you talking about? No circuit is perfectly linear, and no one I knows claims such. That does not invalidate linear theory, nor denigrate its utility properly applied. Many circuits are "sufficiently linear," and "care" little about supply rails and efficiency.

> Why are there no sine waves in
> nature? Because nature is bounded by the Big Bang (a discontinuity)

I'm not religious, but you beg me.

Ohmigod!

> In other words, tedious appeals to artificial impositions of purity
> fail at the gate for their sheer collapse of internal logic. This
> kind of stuff appeals to arm-chair theorists who find themselves
> impotent to perform.

Suit yourself. Go ahead and apply theory to that for which it was not designed to handle. In fact, you don't do it -- your own example about testing your PA stated absolutely nothing about linear theory, or output impedance of the device. I use (apply) linear theory a good share of the time. That doesn't mean I don't recognize its limitations as a theory (a model).

> > The point is that the output impedance is

Wow. More importantly, engineers select appropriate models for the design task. They don't bother with ones that have no application to the task at hand.

Yes, load line matching is certainly a first principle.

> >The simple linear model is perfectly okay for small
> >signal devices. It isn't okay for large signal devices.
>
> And yet there is no substantive illustration to prove this ambiguous
> point. What constitutes small, and what demarcates large?

Maybe you didn't read those first principles quite closely enough. Nor have you read this thread well. Large signal amplifiers -- i.e. power amplifiers -- "care" about DC to RF efficiency and supply rails. Small signal amplifiers don't "care" about that.

> Such nebulous thinking clouds the
> obvious observation that the full range
> of devices themselves operate on only one principle.

Quite afraid to ask, but being brave, I ask: what "one principle" is it "that the full range of devices themselves operate" upon?

> What is limited
> is the human component of their perception, not the physical reality
> of their operation.

And you critiqued me for nonsense.

No, it is a fact of the matter. You don't know what the equipment does.

> >Thevenins and conjugate matching (for maximum power transfer) are
> >explicitly linear small signal device models. Their use in RF PA output design
> >is a misapplication.

> These statements are drawn from thin air.

No, for PA design, the thevenin impedance of the output source never enters "the equation." Thus pretending that it "is there" is an unfounded assertion. You asserted thevenins to PA design, now prove it. You can't.

What utter ignorance of what has actually been written. In my very first post I described the first order cut of matching technique.

> >*You* brought up Thevenins and armchair philosophy regarding it, not me.
>
> I rejected it as an unnecessary filigree,...

Exactly. It is not necessary. But you brought it up, and Ken implied a simile with "impedance matching." You might wonder why it is not necessary. You might even ask the question wondering if the reason it never shows up is because it would be a misapplication of the concept.

> ... but I notice in the quotes

Hi Jack

Just got back from HomeDepot where they had 5/8"x8' copper rod and bronze clamps as well as #2 copper wire. I'll use two bronze clamps on each so I can daisy chain the #2. I can put one on the corner of the house and two more along the way to the service ground. That will make four including the station ground around the house and one out at the antenna tuner.

Thanks for your help

jtm (risk averse...)

Mmm-Hmm

On Wed, 23 Feb 2005 19:08:20 GMT, gwhite <gwhite@deadend.com> wrote:

>RF transmitters are not impedance matched to antennae in the sense of maximum
>transfer of power.

Hi OM,

As I've noted in the past, you can fill a library with negative
assertions without ever offering an answer, eg.:
>RF transmitters are not Nuclear resonated to antennae in the sense of maximum
>transfer of power.

>RF transmitters are not impedance matched to antennae in the sense of maximum
>balance of payments.

>RF transmitters are not cosmically matched to antennae in the sense of maximum
>psychrotropic power.

The list could go on, be completely accurate, and yet never actually
mean anything in the end much as the nonsense you offered from the
start.

You sighed with content at being offered a "relevent
question/statement" Your re-iterative response contains the same (how
could it be otherwise?) slack of precision that started this. Want to
try again?

You could have as easily expressed what sense they ARE matched, but
instead this time offer what Basis of Matching you are attempting to
describe. This is the more rigorous approach that eliminates vague
descriptions and uses standard terms. If you have to query about what

"Basis" means (used by professionals - namely metrologists who can
quantify Output Z of all sources) - then we can skip it as a topic out
of the reach of amateur discussion.

Note:
>Again, RF PA's should be load-line matched.
Does not qualify as a Basis. It is suggestive of one, but because you
indiscriminately mix several Basis within your discussions, it is your
responsibility to be precise. If you can accomplish this, then we can
proceed to review how little it all matters.

Barring resolving any of these issues of precise language, I notice
that you rather enjoy fruitless jousting with them than challenging my
support of Ken's (supposed) statement that you say is your focus:
>> However, responding to the bald statement, I find nothing
>> objectionable about it.
>
>That's because you don't understand the difference between impedance matching
>and ac load line matching.
We will leave that as another dead-end.

3217. 450ohm Ladder Line Dimension and PVC

Newsgroup: rec.radio.amateur.antenna
Date: 2005-03-02 22:16:41 UTC
From: Jim Miller <jim@jtmiller.com>
Message-ID: <1109801801.317042.174310@z14g2000cwz.googlegroups.com>
Source record: 81256

I'd like to run 450ohm windowline inside 1/2" vertical PVC conduit for about 8 feet to minimize the chance of kids messing with it and getting hurt.

The line would come in vertically upwards through two 90° pulls which have a removable plate on the corner, the first of which would have a box adapter bushing to keep the 1/2" dimension. The second adapter would fit to the top of the PVC. This should keep water intrusion out.

Another 90° pull junction would be at the bottom where the line would enter a PVC junction box housing the lightning arrestor and remote tuner. A 5/8"x8' ground rod would be the support for the box to which the arrestor and tuner would be bonded.

What's the edge to edge dimension on 450ohm line?

Anyone done this and experienced big losses?

Should I expect big losses?

This would make for a nice clean installation and relatively stealthy.

tnx
jtm

Playing along with the idea that there is some meaningful fixed Z of the device for large swings, yes you would have to do so to prove the concept. You would need to prove that output Z was the same for driving 1 W into the output as for driving 100 W into the output. I also predict that even the small signal output Z of the power amp will not be that conjugate impedance you think it is for a properly designed PA. (I am not making a claim that it would *never* be so for any PA.)

> Any change in the load, no matter how small, will cause a change in the
> output voltage and the output current.

Likewise, a change in the output Z would do the same thing. Since you're presuming linearity, we can include gain linearity. I.e., the gain with "-10 dB" of drive is the same as the gain with "0 dB" drive. I'll define the 0 dB gain as associated with the 1 db compression point. Since the gain is defined as linear (really fixed regardless of drive), and the load is fixed, something must have "caused" the compression. A way to *model* the compression is a changed output Z as a function of drive. While I realize this is an unconventional view of output compression modeling, I believe it is fair, since you are making the linear presumption. I think this is fair also because the impedance concept is a linear/sinusoid one. Under that presumption, you've given me license to disregard distortion.

> From these you can calculate the
> output impedance at the current operating point.
>
> When a transistor is operating under large signal conditions into a tuned
> load, there is still an output impedance and this impedance still
> discribes what will happen for small changes in the load.

Let's do another example.

Say the device we've selected has an Imax rating of 1 amp and a generator resistance of 100 ohms. Per standard linear theory, we do our norton model of Igen in parallel with the 100 ohms. Under standard conjugate matching theory, we should load it with 100 ohms.

Now with the 100 ohm load, we get a 50 V peak for Imax = 1 amp. But what if both our DC supply and device breakdown won't allow this? We have a practical limiting Vmax not at all included in linear theory. Due to breakdown or supply rail concerns, we'll see our Imax quite short of the 1 amp we expect when the device is loaded with 100 ohms. We won't be getting all the power out of it we "expect" because of practical limitations not built into linear conjugate matching theory.

How do we select the best load, since conjugate loading clearly does not use the device to its full potential? We seek Ropt, or what is commonly referred to as the load line match.

Ropt = Vmax/Imax

where Ropt << Rgen, if not

(Rgen + Ropt)/(Rgen*Ropt) = Vmax/Imax

So even looking into the PA output in the small signal sense (or tweaking the impedance as you suggest), we won't likely see Ropt = Rgen, because we are dealing with some practical design limitations not accounted for in linear theory.

Perhaps a couple of quotes from Cripps would be nice:

http://www.amazon.com/exec/obidos/tg/detail/-/0890069891/

"The load-line match is a real-world compromise that is necessary to extract the maximum power from RF transistors and at the same time keep the RF voltage swing within specified limits and/or the available DC supply." p13

"A final note here concerns the nebulous and highly questionable concept of large signal impedance. The reason for the load-line match is to accommodate the maximum allowable current and voltage swings at the transistor output. That says nothing about the impedance of the device, which remains the same throughout the linear range. Once a device starts to operate in a significantly nonlinear fashion, the apparent value of the impedances will change, but the whole concept of impedance starts to break down as well, because the wave forms no longer are sinusoidal." p14

No, the purpose of the power amp is to deliver power, not extract it.

Don't bother with the over simplified Class A case. RF power
amplification is rarely done class and and it is a digression from the
actual topic.

[...]

>this simplistic example.

At some point as you decrease the resistance, the output will drop to zero
as the amplifier fails or it will start to decrease in some more
controlled manner as the protection circuits take control. If we assume
the latter case, it is easy to see that the power reaches a maximum value
and then decreases as the resistance is lowered. The point at which the
power is at the maximum is the point at which the load is matched. If you
make a small change in the load and observe the voltage and current when
that small change is made, you will see that that is indeed the output
impedance of the amplifier. I think this is the part you are not
grasping.

Yes, I stand by and have just in another part of the thread once again explained that indeed the impedance is matched. ie: If you make a small change in the impedance in any direction the power decreases. Increasing the resistance is the obvious one. The other three are because the protection circuits act. The OP had a completed transmitter he was connecting to a length of wire.

Well really, once the device and supply have been determined, we can indeed view
it as extraction. We'll load it to extract the most. If you want to mince
words and call it "deliver," that is fine.

Well, class A is certainly done. Two cases are where the extra little bit of
linearity is desired and at high frequencies, were PAE starts to take a bite as
the gain drops below 10 dB.

No, this is exactly where I'm saying you are incorrect. You are not getting the practical limitations and are mistakenly applying linear concepts. It doesn't work if you want to extract maximum power from the DC supply through a real device, converting the DC power into RF power.

Driven to max swing, this is true. But it is because of asymmetrical clipping, not because of conjugate mismatch. For lower drives, what you say won't necessarily be true *unless* you've mis-designed according to conjugate match ideals. Your argument is circular.

If you design for conjugate match, you're right. I'm saying: don't do that. If I design for load line match and you design for conjugate max (both pf us using the same device and supply), I will get a higher peak power than you will. However, you'll get to be right about how your amp acts regarding diverging from conjugate load. But it is irrelevent: you made a fundamental mistake.

Hi Jim, The ladder line I have is .931 inches edge to edge. As such
I would not recommend trying to stuff it thru 8' of 1/2" PVC. I would
at least use 1", and even then you will have some compression of the
ladder line. Changing the spacing of ladder line will change its
characteristic impedance.
Thinking about it, if you force ladder line into 1/2" PVC you will
have to distort it into a "U" shape, and have a bad time trying to fish
it thru the PVC.

Hi OM,

This match, as you speak of, is probably remote from any probability
you are likely to encounter with the antenna options you describe in
your posting. However, there are other merits:

>a proper shielded connection to my receiver should help minimize
>stray RF noise.

Presuming you mean to terminate the far end shield connection to
ground.

>I'm guessing the real advantage would be realized if I had a good RF
>ground at the receiver and/or balun. This will be sort of tricky. I
>don't even think I have copper cold-water pipes anywhere, and running

OK, so we strike out those as options not available to you.

>I've heard of people using
>houseplants for poor grounds when no other was available, and I have
>many kilos of wet earth on the balcony.

Don't even think of it. Ground does not mean wet mud.

>I've seen a neat artificial ground/antenna tuner from MFJ (I think)
>which seems to offer a lot of bang for the buck. It even has multiple
>inputs for high-Z single wires. Would this be useful for SW?

Certainly, but you would achieve just as much with a simple tuner
(cheap one without the transmitter meters). In fact, this tuner is
generally very necessary to keep local AM stations from desensitizing
your receiver. This is a common plight suffered by many who would
otherwise think they were doing pretty well, but just need more
antenna to get those signals others are reporting.

>Finally, I'm probably just going to wind my own balun out of a ferrite

> Do I wind the primary first around the whole core, and then the

>secondary on top of it?

What you are describing is a conventional power transformer - NOT the same thing as a Transmission Line Transformer. What you should really concentrate on is what is called a Transmission Line Choke (perfectly accomplished using a 1:1 Current BalUn/UnUn).

G. White wrote:
"This example is intended to be illustrative rather than exact."

Nobody contradicts that maximum power from an amplifier requires an impedance match, so far.

Nobody contradicts that efficiency in an ideal Class A amplifier can never exceed 50%, so far.

Some texts show waveform distortion typical of a single-ended Class A amplifier and note that "maximum undistorted power" requires a load impedance 2 to 3 times that of the amplifying device.

G. White gives a peak to peak voltage of 20 and a power out of 5 watts. RMS volts are 7.07 in this case. The load then is the square of the volts divided by the power. This is 50/5 or 10 ohms for the load. If this matches his amplifier, 5 watts is the maximum output.

G. White said that he did not consider the output-Z of the amplifier in its loading. Ignoring an amplifier`s impedance does not make it go away. Ignoring an amplifier`s impedance does not revoke the maximum power transfer theorem, either.

Best regards, Richard Harrison, KB5WZI

All,

Thanks for the replies. One clarification; I meant "ground rod" in 5.) above, NOT "lightning rod". It should read:

5.) Finally, consider an amateur antenna on a pole, located some distance from the service entrance of the house. Let's say there is a copper cold water pipe right at the service entrance. Is it wise to place a ground rod (or rods) right under the antenna, place an arrestor on the coax there and then another arrestor where the coax enters at the service entrance? Is a ground wire needed between the remote ground rod and the cold water pipe?

Thanks,

-JJ

3230. Why a Short Lightning Ground?

I can understand why we want a short connection between the station ground (the bonded chassis) and earth ground in the case of an RF ground, especially for unbalanced antennas. But for a lightning ground, I am not sure I understand why we want a short connection between station ground and earth.

Let's take the example of an operator with whose only choice is a second story ham shack and an antenna mounted on a pole some distance from the house. If a balanced antenna system is used (so we don't need a good RF ground) and the coax has an arrestor placed at the service entrance ground where the shield is connected (cold water pipe in basement), why do we need a ground wire at all? (The coax would run from the antenna to the basement level [where grounded] and then up to the second floor.) The chassis' can be bonded together and the bond point can be connected to earth ground through the coax shield. The lightning is not going to travel up to the second floor to get the radio when it has a low impedance path right at ground, is it?

Richard, your method of measuring internal impedance of an amplifier sounds interesting. (o/c volts divided by s/c current)

At present I have no facilities to make such measurements.

Perhaps a few curious readers, who do have facilities, might make crude measurements on their HF rigs and report approximate impedance values on one or two bands on this newsgroup. Some sort of average could be obtained.

Reg, G4FGQ

Jack, isn't this getting a little over-the-top? I have to dig a 2
foot hole, get an 8 foot rod totally buried in that hole -- and then
what, to bond different rods together, dig a 2 foot trench from rod to
rod to bond them together with strapping?

And what about all the corrosion on the buried rods and strapping?

Who does this sort of stuff !! ??

I understand you're quoting from codes, but does anyone "residential"
really do this stuff?

3233. Antenna philosophy

Newsgroup: rec.radio.amateur.antenna
Date: 2005-03-03 01:06:32 UTC
From: "Joe S." <nobody@nowhere.net>
Message-ID: <d05nul097i@news3.newsguy.com>
Source record: 81176

In 1996, I disassembled my antenna farm that graced the 3-acre plot where we lived in Manassas, VA:
-- 40- and 50-foot Rohn towers
-- two 135-foot dipoles each center-fed with ladder line
-- TH7
-- assorted VHF and UHF beams
-- 40-mtr inverted Vee

Bundled it all up and moved from Virginia to Tennessee where I moved into a restricted subdivision. The antenna farm stayed bundled up in the crawl space.

In 2003, sold the house and moved into an apartment at which point I sold the antenna farm for a fraction of what I paid for it.

Now, in 2005, living in an apartment on the Mississippi Gulf Coast and trying to scrape together the money to build a house on a 100 x 100-foot lot where maybe I can put up a short dipole but will not be able to have a tower.

So -- what's the point? As I sit here and read the debates about this wire, that vertical, some other yagi, yes/no on the Carolina Windom, advice on an antenna for a 10-acre plot -- I can't help but think: If you have an antenna, thank the gods because any antenna radiates better than no antenna.

> between station ground and earth.

Because a large portion of the frequency spectrum of lightning is at RF. Therefore the inductance of a conductor, not just it's dc-resistance, is critical to maintain as low as possible. This is done by the shortest, lowest impedance connection possible to the earth. The potential from all bonded equipment in a shack and the potential at the grounding electrode of the station ground should bever be more than 4' apart in elevation, and even that is a stretch. 1' would be ideal!

>
> -JJ

Good that you brought that up. A second story ham shack is the most difficult, and almost an impossible location to safely provide a low impedance ground for. Feedlines supplying a second-floor station should never be allowed to enter from an above ground elevation. Think of inches of elevation being equal to hundreds of volts each. A few feet above ground can easily be 10,000v potential above ground. As long as the conditions you described are followed, the feedlines have a safe path up to a second story, wrt ground potential rise or attachment of lightning to a nearby antenna.

There are other issues that make the second floor difficult to protect, but education can solve most of those problems. Lightning striking the nearby antenna tower, telephone pole, tree in the yard, rooftoop, etc, can also induce massive energy by electro-magnetic induction on house AC wiring, phonelines and feedlines inside a structure. It won't matter if they were grounded on the first floor if the energy in also induced at the second

floor level. Bonding, and a ground system, and adequate surge protection control EMI from lightning. The problem that relying on a copper strap connection to ground from 13' above ground is, it still allows a LOT of potential when confronted with thousands of volts of potential from EMI. "Wire" to ground from the second floor is useless at RF frequencies, and even wide copper strap allows a dangerous level of potential to develop. But it is better than nothing, because the electrical wiring on a second floor is at a frightening potential wrt ground. If bonding and a lower impedance path to ground is not provided, the prospect of at least minor damage is possible from any nearby strike. Disconnecting the feedlines outside (only) do not help prevent EMI damage at all. The wiring still carries it, and feedlines still connected to the radios carry it as well. A Drake R8B I own was originally crisped in a friend's second story shack, and it's feedlines were disconnected outside. The entrance point of the damage? The RG-8X feedline! Where did the lightning strike? 200' away on the tower. The connection to AC ground (a horrible potential between earth and AC ground exist on a second floor, remember?) was established via an AC powered sound board that the Drake was connected to via speaker wire connection. My friend thought disconnecting from main AC power and breaking the feedline connection outside was enough to protect equipment. That's not always the case.

I vote best of best. I use one for 40 and 80 meters at 40 feet and have no problems tunning. I also get good reports, and get into Europe on 40 if the band is right. It is a good general purpose antenna. It is probably in the same class with the G5RV, but is a cleaner installation.

Message-ID: <m-5FD012.20161602032005@news.verizon.net>
Source record: 81174

I was wondering all this neet posting about lightning

i understand that lightning wants to find path of least resistance

if my antenna is grounded, so over other objects on the roof,
including the brick building itself nearby trees etc wouldn't my
antenna then become the 'best' ground ie path of least ristance and
thusly ""attract"" the lightning

i get confused since, my antenna being a good conductor and grounded
(both pairs when not using it) will thereby dissapate ''static'' or
ionic buildup and so i think wouldn't that sorta make lighting not
become super attracted to seek it out??

dunno which takes the lead here??

thanks

m

Hi Bob, you're right few people follow NEC code to any degree unless an inspector is going to follow. And I hope I pointed out a couple examples where code was changed or written because of convenience, not science (the 2' below grade level and non-continuous requirement). So in some cases following code is not the best practice (it needs to be exceeded) and in other cases is just not practical or possible. You be your own judge there. Anyone who follows the topic knows why the rules are there, and that in the case of a casualty, an investigation may assign blame whether code was followed or not, but certainly if it was not.

The knowledge gained and effort made to protect property is certainly more important than splitting hairs about code that is a moot point for most.

If you ran the wire around all 4 sides of the house, you could build a horizontal loop. They work great, but be aware that you are living "inside" the antenna and RF exposure could be a problem.

I would run the wire around just 2 sides, the two sides least used for living and sleeping.

Try this simple test.

Tune your receiver to a part of the dial where there's no station. Disconnect the antenna from your receiver. If the noise level drops, impedance matching won't help your signal/noise ratio, it'll just make everything louder. You can accomplish the same thing by turning up the volume control.

J.J. wrote:
"---why do we need a ground wire at all?"

Three reasons:
1) 50/60 Hz safety
2) R-F circuitry or suppression
3) Lightning abatement

Powerline frequencies have such wavelength that phase and voltage are the same everywhere along a line in any particular vicinity. Wire inductance is of little consequence.

Balanced R-F circuits don`t rely on ground wires to convey signal between points. Transmission lines do this. Ground wires may be used to supress some undesired R-F appearances.

Ground wires are essential to lightning abatement as the earth is nearly always part of the circuit.

Best regards, Richard Harrison, KB5WZI

The point is, that some people are satisfied with any antenna that radiates. That's fine, nothing wrong with that, and it looks like that describes you.

Some other folks are interested in making an antenna that radiates as well as it can given whatever constraints that are applied (size of yard, size of budget, directions of interest, etc.). Others are simply interested in learning more about how antennas work. Those two groups are the folks who usually hang out here.

You'll find the same thing on other newsgroups -- people in the photography newsgroups aren't primarily snapshot-takers, the ones in the (amateur) homebrew groups aren't the appliance operators, and the ones in the (beer) homebrew groups aren't the Bud Lite swillers.

You might find topics which are more interesting to you on other newsgroups or venues.

Some of Motorola's devices might actually be able to stand
Reg's little test. The MRF150, for instance is advertised as
being able to withstand a 30:1 VSWR at all phase angles. I
think Reg should offer to pay for any damage sustained as the
result of this test.

Joe, I live in an apartment and I use an MP-1 clamped to my patio railing.....I get out from middle Tennessee. I even have the occasional contact on the west coast on 40M phone. I try to keep the power down to about 60 watts or so.....don't want the "Worked all Stereos" award. There is hope. I may consider the ATAS-120 to work with my FT-897.....Don't give up.

RG> Yeah - isn't that why the TOOB amps had those taps? So you could get
RG> that rich, full-bodied TOOB sound? ;-)

No, the taps are there to maximize the power output. If one uses the
8 ohm tap with a 4 ohm speaker the power is reduced and the same if
one uses a 16 ohm speaker. Audio output matching has little to do with
plate resistance in a beam tube or pentode. It has everything to do
with plate voltage swing and maximum plate current. The less plate
resistance the more power can get to the load. Beam tube curves look a
lot like a transistor's collector saturation curves.

However, some tube amplifiers had a current feedback control which
would increase the output impedance to equal the speaker's. Needless
to say it severely reduced the speaker damping resulting in exagerated
frequency response artifacts.

I apologize if I misinterpreted his lament. If the problem is that the current discussions involve antennas which would be impossible for him to construct, I suggest going to groups.google.com and search past postings on this newsgroup for "limited space", "apartment", "stealth", "invisible", "attic" and the like. Although not on the plate at the moment, there's been a great deal of discussion about limited-space antennas on this group in the past, and a lot of good ideas and suggestions have been offered. And I'm sure a lot of folks would be glad to offer more if asked.

Cecil,
Presumably you hadn't heard of Ohms Law.

The internal resistance of a generator is independent of its internal voltage. Just reduce the drive level to some small, no particular value, and stop making excuses.

(Somebody will say it IS dependent. But we are interested only in ball-park accuracy. And in any case the operating point will be within the normal range of operation between no-drive and full drive, or between no modulation and full modulation.)

That might work better for Class-AB than Class-C. If one
reduces drive level on a Class-C, one is reducing the 'on'
time of the device, thus changing the internal impedance
probably somewhat inversely proportional to the 'on' time.

If I remember correctly, my IC-706 would not fold back
under any load condition when run at minimum power.

Asimov wrote:
"I was confusing it with Class B which does warm up the heatsink>"

True. Class B amplifiers can be single-ended for R-F if used with the right tank circuit to supply the missing 1/2-cycle. More often they are push-pull to reduce harmonics.

SSB final amplifiers are biased to near current cut-off. During modulation gaps, current falls to nearly zero. When current is zero, so is the dissipation.

Reg mentioned the blistering heat of the 6N7. Thai`s my recollection too when getting nearly 10 watts of audio from the small twin-triode octal-based metal tube. Reduce the audio volume and the heat is reduced simultaneously.

"wouldn`t my antenna then become the "best" ground or path of least resistance and thusly ""attract"" the lightning."

That seems right and conductivity does not have to be high. Ben Franklin found the conductivity of twine sufficient. He drained charge from the atmosphere by placing fis kite high.

Height is shown to attract lightning bolts to grounded towers used for various purposes. Many are hit by nearly every passing thunderstorm. Towers take lightning bolts. They don`t always if ever discharge the earth and atmosphere in their area to eliminate hits. They do seem to divert strikes in their vicinity and offer some protection to their surroundings.

I`ve spent years in broadcast plants and seen many lightning strikes. If you build it they will come.

Saw a program on lightning a year or so back that described the mechanism
involved in setting up a lightning strike. Every raised object in a fairly
large area below an accumulating cloud charge
sends up a stepped "leader"of opposing charge, all these "leaders"
advance in steps that also zig and zag randomly upward. If I remember
correctly the charge in the cloud is also sending out
multiple feelers in a zig zag process. When one of the clouds
feelers completes a circuit by meeting a leader from the ground
the circuit completes and all hell breaks loose. It's all relatively random
and the leader from a golfers head may just connect before the leader from a
much taller tree or tower connects. if he's a lucky golfer the taller stuff
will make the connection. I've seen weather service warnings lately
indicating that anything within a 25 mile radius of a stormclouds center has
a chance of winning the electrical
lottery. When I see lightning as I'm mowing my 7 acres here in southern
Oklahoma, I now shut down and make for the house.If I have an inkling we're
gonna see weather I bag the terminal end of my various coax connections
before the weather starts and coil them outside away from the house

You can always operate from the car...Seriously...If I had no shack,
antennas, etc, I would still have a decent mobile rig. You can sit
in it, or just park it in the driveway, and run a coax to it, from

house, garage, etc...I've done the "remote mobile antenna" thing many times when camping...I'll sit the rig on a picnic table, and run coax to the car antenna. Works better than you might think. The higher bands, very good. MK

Hi Jim,

It is the weight of the wire times the arctan of the angle the sag of the wire depresses from the horizontal if I recall correctly.

Hi Richard,

From "Reference Data for Radio Engineers," the breaking load for #18 Hard-Drawn Copper is 85 pounds. The weight for 88 feet of this wire (at 4.9 pounds per 1000') would be 0.43 pounds.
>
>Many issues are involved in tensioning. For calculations see Ed Laport`s
>"Radio Antenna Engineering" page 346.

Simple Trig would reveal that with an 88 foot catenary with a 5 foot sag would develop roughly an angle of 6.5 degrees below the horizontal. My earlier post employing arctan was in error. It is the sine of the depressed angle used as a divider into half the weight (we are presuming this is a symmetrical dipole) that describes the tension. The sine of 6.5 degrees is 0.113. The tension in the wire then becomes 0.215/0.113 pounds (1.9#).

Trying to flatten the catenary is where tension becomes increasingly stressful. If you attempted to hold the catenary to within 1 foot of flat, then this would be a depression of 1.3 degrees, resulting in a divisor of 0.022. The tension in the wire then becomes 0.215/0.022 pounds (9.5#).

If we were to add in the weight of the transmission line drop, RG-58 comes in at roughly 0.029 pounds per foot or RG-11 as much as 0.096 pounds per foot.

Let's ballpark the last dipole with 1 foot sag to hold up 40 feet of RG-11 (whatever the practicality, and irrespective of the center being held up, we are considering only a two point suspension). The added weight of the cable comes to 3.84 pounds. The tension in the wire then becomes 2.135/0.022 pounds (97#).

The wire snaps.

Richard Clark wrote:
>

> As I've noted in the past, you can fill a library with negative
> assertions...

The troublesome assertion is not the negative one. It is that RF PA's are conjugate matched. Neither you nor Ken has provided a single example of such a design that also extracts the maximum amount of "linear" power from a device and essentially its power supply (after all, that is what it is: a _power_ amp). Your example said nothing about output-Z, which suggests you have no clue, since you didn't even remotely address the issue.

For Ken's part, he recently obfuscated by dismissing an example that was primarily intended to be illustrative, but yet holding the salient points. He completely ignored (or didn't understand) the clipping issue. Further obfuscation was provided by talking about "protection circuitry," which may or may not exist in a circuit, but adds zero to a discussion regarding how the PA is to be loaded. "Protection" is a non-stater because the PA is either off or impaired.

Ken's argument is circular. He say's that if a design is done for conjugate match,
then it will behave as if it is conjugately matched. Well of course (or at least sort of under specific test conditions and circuits)! It is self-fullfilling prophecy but it unfortunately makes no statement regarding obtaining the maximum power out of the circuit in the sense of turning DC power into RF power (yes, *extracting* power from the DC supply and transformed to RF). This is paramount to PA design. To use the device to maximum efficacy, as Cripps puts it, a load-line match is needed. Ken's "conjugate match" design won't do that, and that's why PA's aren't designed that way.

The bottom line is that if I design an amp via load line techniques using the same device and power supply as Ken (him using conj-match), my amp will deliver higher unclipped PEP than his. That is the factual result you resist. Now if you want to pay for extra power and big devices, that's your business--go ahead and attempt to conj-match your amp--but engineers who design PA's don't do that.

Another idealized and hypothetical example to elucidate the load-line principle is offered.

Let's say we have a 10 W FET we'll build into a class A circuit. An RF choke is used to supply drain current. We DC bias it to Vd = 10 V and Id = 1 A. Just for argument sake, let's say it has a constant internal resistance of 110 ohms and the device will break down at 25 V. According to the most idealized and

standard load-line theory, we should load it to rL = Vd/Id = 10 Ohms. This idealization includes the definition of positive and negative clipping -- whichever comes "first" -- of being the operational limit for output voltage swing. Clipping is associated with severe distortion.

Since we need rL to be 10 ohms, and Ri = 110 ohms, we need to make the actual load resistor equal to: RL = 11 Ohms. Let's check that result and see if it meets the clipping constraint for maximum available power.

positive swing = Id*rL = 1*10 = 10 V
negative swing = Vd = 10 V
Power delivered to RL: Pload = 10^2/(2*11) = 4.55 W
The efficiency is a little under 50% because of the internal resistance. Note the Load resistance is decidely not the conjugate of the internal resistance.

Let's spot check the load to see if it at least appears to be the peak available power, by testing two loads "immediately" on either side of our optimum 11 ohms.

Let RL = 10 ohms
positive swing = Id*rL = 1*9.17 = 9.17 V
negative swing = Vd = 10 V
Since we positive clip at 9.17 V, we are limited by our design clipping constraint to only driving the PA such that 2*9.17 V is the maximum available voltage swing.
Power delivered to RL: Pload = 9.17^2/(2*10) = 4.20 W

Let RL = 12 ohms
positive swing = Id*rL = 1*10.82 = 10.82 V
negative swing = Vd = 10 V
Since we negative clip at 10 V, we are limited by our design clipping constraint to driving the PA such that 2*10 V is the maximum available voltage swing.
Power delivered to RL: Pload = 10^2/(2*12) = 4.17 W

Sure enough, the power peaked at a load of 11 ohms, just like load-line theory says it will. Now let's see what the available power hit of conjugate matching is.

By definition, conj-match insists RL = Ri = 110 ohms. Again we are limited in our clipping constraint by static drain current, and supply voltage, specifically 10 V.

Our negative swing limit is, as ever, 10 V (the drain voltage).

positive swing = Id*rL = 1*55 = 55 V

This would breakdown the device, but the lower negative swing will force us to back down the drive to meet the design defined clipping constraint.

Pload = 10^2/(2*110) = 0.455 W

Conjugate matching resulted in a 10*log(0.455/4.55) = 10 dB available power hit. Power amplifiers are not designed with conjugate matching in mind. You don't need to re-invent the wheel. Just follow well established principles when doing cookie cutter PA design.

> The list could go on,...

LOL. Given your pattern, I am sure it will.

> You sighed with content at being offered a "relevent
> question/statement" Your re-iterative response contains the same (how
> could it be otherwise?) slack of precision that started this. Want to
> try again?

Not really. The problem isn't precision, it is you can't, or refuse, to comprehend what is being said, which I presume is why you instead write with the most bizarre terms and phrasology that has nothing of import to the topic at hand.

> You could have as easily expressed what sense they ARE matched,

For what seems like the billionth time now: they are load-line matched.

> ...but instead this time offer what Basis
> of Matching you are attempting to
> describe.

I've given a didactic example (actually a couple), you just don't--or more likely won't--get it. If you don't like my example, you can refer to Cripps, who is considered one of the preeminant RF PA experts in the world.

Even more simplistic is Malvino's discussion on pp177-185 of the first edition ((c) 1968) of "Transistor Circuit Approximations." It is basically a technician level description, so perhaps it is well-suited to you. In academics, load-line theory is presented down to tech level courses and up across to engineering. That some engineers and techs aren't clear on the load-line concept for PA's (or *any* circuit needing a wide symmetrical swing) is notwithstanding.

> This is the more rigorous approach that eliminates vague
> descriptions and uses standard terms. If you have to query about what
> "Basis" means (used by professionals - namely metrologists who can
> quantify Output Z of all sources) - then we can skip it as a topic out
> of the reach of amateur discussion.

I see you still don't know what impedance is. In any case, it doesn't mean that looking into a properly designed PA output with a network analyzer confirms the conj-match precept, it doesn't.

Impedance is a *linear* conception, a portion of linear theory, and again by definition:

Z = V/I

V and I are sinusoids (phasors). But with power amps, substantial non-linearity exists (destroying the linearity assumption of impedance), thus applying a linearly defined concept to a non-linear milieu is a misapplication. You are attempting, as is Ken, to stuff a square peg down a round hole. Why?

The concept is even questionable for the most linear of the power amps: class A. In any case, given real devices with real supplies, the conj-match ideal is next to worthless. While I could agree that the borderline may be fuzzy

regarding where and when to drop the impedance notion, it still stands that the concept is not useful in determining how to optimally load an RF PA.

At this point you own the conj-match assertion as much as Ken. Prove it! You can't because it is fundamentally incorrect.

> Note:
> >Again, RF PA's should be load-line matched.
> Does not qualify as a Basis.

Load-line matching is such a basic electronic concept it is unbelievable how oblivious you are to the concept. Read a basic book. Don't rely on me: look it up and do your own design!

> It is suggestive of one, but because you indiscriminately
> mix several Basis within your discussions, it is your
> responsibility to be precise.

You just like to hear yourself talk. I've been explicit and precise. You just don't know anything about the elementary electronics principle of load line matching. I presume this is why your comments have zero substantive responsiveness.

> If you can accomplish this, then we can
> proceed to review how little it all matters.

If you keep ignoring what I've written, and that which is written in elementary electronics texts, you can remain happily ignorant of understanding the simple-basic-fundamental concept presented. Your choice.

> Barring resolving any of these issues of precise language,...]

The guy ignorant of the definition of impedance and that s-domain theory *is* linear circuit theory (and more goodies) is talking about "precise language." Amusing.

> I notice
> that you rather enjoy...

No, I don't enjoy it at all. Your lack of electronic understanding is dismal, especially given your tone. It would have been a lot easier for me if Ken hadn't made the erroneous
statement in the first place and made a correct one instead. That would have been my preferance.

> ..fruitless jousting with them than challenging my
> support of Ken's (supposed) statement that you say is your focus:
> >> However, responding to the bald statement, I find nothing
> >> objectionable about it.
> >
> >That's because you don't understand the difference between impedance matching
> >and ac load line matching.
> We will leave that as another dead-end.

I suspect you will. I already understand it -- you're the one who doesn't.

"One of the principal differences between linear RF amplifier design and PA design is that, for optimum power, the output of the device is not presented with the impedance required for a linear conjugate match. That causes much consternation and has been the subject of extensive controversy about the meaning and nature of conjugate matching. It is necessary, therefore, to swallow that apparently unpalatable result as early as possible (Section 1.5), before going on to give it more extended interpretation and analysis (Chapter 2)." -- Cripps, p1

The quote is on Page 1. Swallow it now. Learn something for a change.

A G5RV junior is a 1.5WL dipole on 10m with a
1/2WL matching section. No G5RV that I ever
heard of has traps. I'm assuming you did mean
G5RV instead of G4RV?

>This would breakdown the device, but the lower negative swing will force
>us to back down the drive to meet the design defined clipping
>constraint.
>
>Pload = 10^2/(2*110) = 0.455 W

And the power dissipated in the device is also 0.445 W. Matching
according to the 'maximum power theorem' or conjugate matching, results
in equal power in the PA and load. That's why it isn't useful for power
amplifiers.

Doesn't everyone know that an audio amplifier that id designed to feed
an 8 ohm load MUST have an output source impedance of 0.0000001 ohms or
less. An output source impedance of 8 ohms would dramatically decrease
the electromagnetic damping on the loudspeaker voice-coil - by the huge
factor of .... two!(;-)

Hi folks,

I just bought a batch of Amphenol PL-259 83-1SPs to assemble some jumpers. When did Amphenol shift from 'Made In USA' to 'Assembled In Mexico'? The whole reason for buying Amphenol was to:

A) Enjoy that Amphenol quality. (BTW, they don't even look the same. The dielectric has a cheap milky recycled look and the name and model nr. are no longer stamped into the sleeve ring.)

B) Support products 'Made In USA'.

Ok, this was my two minute rant. Tnx fer listening.

>jtm

This isn't very scientific, but I just pull the wire tight until most of the sag is gone. Never had one break. Also, if using trees for support, a screen door spring at each end, between the tree and the insulator, will keep the swaying tree from snapping the doublet.

I think it is 1A*10V - 0.455 W = 9.545 W
^^^^^^ ^^^^^^^
DC input Power
Power delivered
to RL

The resistance dissipated in the "internal AC resistance" is equal to RL in the conj-match condition. Of course, we're ignoring input power here, which is "small" when the gain is > +20 dB.

> Matching
> according to the 'maximum power theorem' or conjugate matching, results
> in equal power in the PA and load. That's why it isn't useful for power
> amplifiers.

Amusingly for my hypothetical class A conj-match example, the "equal power dissipation" isn't such a big deal, since it is class A and the fractional power dissipated in either the internal AC resistance or the external load resistance is rather small compared to DC dissipation (less than 10%).

> traps. Did I miss something there?

Hi Charlie, A 5-BTV with 72 radials will have about the same take off angle as a full size vertical with 72 radials on a given band. This is assuming the 5-BTV is operated as a 1/4 wave, current fed vertical on all bands. If it is used as something else, say a 1/2 wave voltage fed vertical on a given band, then the TOA should be about the same as a full size 1/2 wave vertical.
As you can tell by other posts, actually measuring the TOA will be difficult. If you could model full size versions of the 5-BTV on the bands of interest on a program such as Eznec, you could find out your TOA. As Reg asked, when you do find it out, what are you gonna do then?

>If I remember correctly

you don't.

there are exceptions, but in most of the cloud-ground lightning the 'stepped leader' starts down from the cloud. it progresses downward in 50-100m steps bringing charge down from the cloud with it as it progresses (most often negative charge). as it gets closer to the ground it attracts the opposite (usually positive) charge under it, when the field strength is high enough streamers start up from the ground and connect with the stepped leader and the bolt that you see is triggered. streamers from the ground are normally not stepped, they are a single breakdown between the ground (or some other object) and the downward leader usually no more than about 100m long. the final attachment point for the stroke depends on which streamer coming up connects to the leader coming down first.

don't ever say that lightning won't do something. the voltages and currents
and frequency range combination in lightning can do things that are often
hard to understand. it will go up, down, and sideways, often at the same
time. and just because it hits the ground doesn't mean it won't come up
again somewhere else and still be deadly or destroy equipment.

AMEN on that! I have been on both sides of it, right now i have a big
aluminum farm, but i have been in apartments and still found a way to
operate. if nothing else load up the bedsprings and chat around town.

The scariest thing I ever heard of lightning doing is
killing someone out of a clear blue sky, coming from
clouds that were hidden by mountains.

Cecil, the "bolt from the blue" is a fairly common way for Americans to be struck and injured or killed from lightning. In a few cases each year, witnesses offer that there was either no warning that the storm was arriving when the victim was struck, or they had only heard thunder but not seen the storm. Last year I believe there were three such document cases, two of which resulted in fatalities. The National Lightning Safety Center and National Weather Bureau have both recently revised upwards the number of miles from a storm that lightning can be expected to strike. That number varies according to agency but is generally accepted to be at least 10 miles ahead of the storm and an unknown (smaller) number of miles behind it. Agreed is the now universal warning that if outdoors you should find cover immediately when you hear thunder, and not leave cover until 30 minutes have passed without hearing thunder.

A good friend who I have known for years and who provided many professional documents for my lightning systems review over the years was just struck (and injured) last summer. He waited a couple minutes in his driveway in Virginia for the rain to let up a bit, and then made his forty foot "dash for the door". Lightning struck a pine tree next to the driveway just then, and it struck sideways into his shoulder and out his feet onto the wet driveway. His wife found him unconscious a few minutes later, and he was fortunate to survive and make good recovery so far. More than half of all survivors of lightning strikes experience mental and/or physical disabilities or complications following the incident. Another good friend was in his Virginia workshop three summer ago when lightning struck the tower, and he was the lucky survivor but unfortunate witness to massive damage, some of it explosive, both to the room he was in, and other

buildings on his property. after a lifetime of close calls myself, it was my close friend's experience three years ago that finally helped me get the message and change the way I operated.

Sure. My Elmer and neighbor had an acre and lots of bux but he still
liked his "mobile" rig.

http://www.qsl.net/n7ws/w7uvr.jpg

This was "state-of-the-art" in 1958.

Full tilt with a high level modulated 4-1000A. Thirty foot "tower"
and 2 el. beam for high bands and remotely tuned verticals for lower
bands.

I tried all that scientific formula stuff, and the KISS stuff. But neither made the tree rats happy.

So my answer is; put it up until the squirels find the line and chew it in half, then put it back up.

Greetings
Does anyone know if typical schedule 40 PVC pipe is UV resistant? I
have some antenna projects in mind that will be built from this stuff.
I suppose I can paint it for some extra protection, but I was wondering
if it is necessary?

Thanks
Jim/K2TL

3299. Re: 1/4 vs 1/2 wavelength antenna

Wow this is a long thread. Don't really know where I should put my two bits in, but here it goes.

I have designed several RF PA sections in the past. 500MHz at about 50W. Pretty easy stuff if you have the right tools and know how to use them. The tools I like using for matching the power output FET is two triple stub tuners. One on the input of the FET and one on the output. So it goes...pre-amp (50 ohm output) -> stub tuner -> FET -> stub tuner -> 50 ohm dummy pad -> spectrum analyzer. Then just tune the stubs for the performance you desire, these include: efficiency (thermal issues), harmonic content, spurious emissions, load VSWR considerations, cold start, ect. Then remove the FET and look into the triple stub tuners with the network analyzer. Model and duplicate the network out of discrete components that can handle the voltage/power, send the design off to the enviro test lab, and head home early for the day.

Cheers,
Thomas

I went on a tour of a TV station tower site last year, and they had a lightning suppression system that had a number of rods with a lot of fine metal (wires?) hanging off the ends - they looked a bit like a cheerleaders pom-pom. The individual rods hung from the sides of that tower at various heights on the tower. Height was either 1000 or 1200 foot IIRC.

The station engineer noted that although it was still a noisy place when a storm was approaching, it was no where as exciting as it used to be!

And yes, it did protect the area around the tower.

I was very impressed with the mechanics of a large tower, such as the huge suspended weight/pulley system on the guy wires, The strange elevator that takes people up to do maintenance on the tower and guy wires, the icefall protection structures (the engineer lost a car once), and of course the foot thick solid copper jacket coax!

Not having a lot of space for wire antennas (50 feet at best) would it be better for me to use an endfed zepp (50 feet) or a double zepp (25 feet each leg) ?

On the endfed zepp there is one side of the latter line that its not connected to the aerial, on the other end (in the shack) where does that end connect to...ground or should it be connected just like any other latter line on the tuner ?

Just trying to get the best results out of a small space.

Thanks

Gil

It's not bad, some of the early stuff (1970's/1980s) for an installation --
it is a lighter shade of gray today.
The last batch that I purchased a couple of years ago was silk-screened
(yellow) on outside as being UV resistant.
http://www.jmpipe.com/electrical.html

Schedule 80 is thicker (and heavier) and rated for outdoor use (and
punishment).

This is from Carlon (a major electrical PVC conduit mfg.)

UV is an issue for all plastic products. Fortunately, there are additives
that are added to plastics to make the material UV resistance. Listed
Schedule 40 and 80 PVC conduit utilizes these additives and are UV
resistant. The sunlight resistance test is found in UL Standard UL651.
Listed product will have an indefinite life period.

Listed Schedule 40 and 80 Conduit have been used in Florida for years
including on rooftops. It is preferred along the coast because it is
corrosion resistant. When used in an exposed environment where there are
changes in temperatures please are sure to use enough expansion fittings.

I think he just meant that damping factor is important in an audio amp.

At least I hope that's what he meant.

He forgot to mention that for that output impedance to be relevant, you
need superconducting wire to the speakers as well as superconducting
voice coils.

Mike,

The IEEE has nearly succeeded in quashing once and for all, the last ditch efforts of a desperate group of snake-oil salesmen pushing Early Streamer Emission (ESE) and Charge Transfer System (CTS) phony-science. The latest trick of these junk-science purveyors was to hire corrupt Russian scientists to publish "findings" that the ESE/CTS systems worked. Every other lightning expert in the world has rung-in on this already, and the theory is totally discredited, and without merit.

That didn't stop some engineers at various plants and stations around the world from trying the systems those CTS snake oil salesmen pushed. The system you described on that tower is CTS. And it never worked, anywhere. Anyone who still defends it today is too embarrassed to admit they paid upwards of 10x the cost of proven Franklin-rod lightning systems, for a totally discredited design that leaves them dangerously exposed to damage from lightning (if it was the only protection system).

A 50 ft end-fed Zepp would be 1/2WL on 9.36 MHz. The quarter-
wave matching section would make it a three band antenna for
30m, 17m, and 10m.

A 50 ft center-fed dipole will work all frequencies from 14
MHz up with a suitable tuner.

Reg
If he knew the TOA could he not ascertain the height of the reflecting layer
using your "hop distance" program:.
I suspect that your program on the same subject has a similar use so perhaps
you could answer your own question.
With my antenna having a TOA of 10 degrees I could work out backwards a
whole mine of information all based around your program, assuming your input
data is correct. Grin
Cheers

I have just come to realise that if one drew a polygon of element phases in
a array
and all elements were 180 degrees to its companion element and excluding the
driven element, the max gain and max front to back will occur at the SAME
frequency!
Until now I was of the understanding that these two max figures could not
occur at
the same frequency. Is there anything written about this possibility?

Dear Gil,
At the tuner, the two sides of the ladder line connect to the balanced line terminals. Don't worry about the fact that up at the antenna, one side of the ladder line connects to the antenna and the other side is open. That was one of the best antennas that I ever had as a kid. Ideally, the length of the antenna should be 1/2 wavelength for this configuration.

> current draw on my alternator ie would I need a bigger alternator for
that
> etc.

The alternator is probably ok, being you probably won't even be
50% duty cycle...The early 520's will work on 12v, but they are
sort of weird, being the voltages and regulation are not quite
as good as on 117v. But it will work. Probably at a reduced
power compared to 117v. Yea, kinda large too. Would have to
keep it on the seat, or floor...You might wanna save for a 12v
rig. Much easier to deal with mobile and portable. I had a 520
I rebuilt about 4-5 years ago..Sold it to a friend, and he ran
it mobile for a short time...It worked, but was kinda funky, and
he got a TS-450 shortly after that...He liked the 450 much better
when mobile, needless to say...I ran a IC-730 for a long time, but
the display board pooped out, and I couldn't get the part..:(
"goofy small 9 pin transformer in the dc-dc converter circuit"
So I broke down and bought a IC-706mk2g. I still plan to fix the
730 one of these days, when I get another junker to get the part.
Shame for it to collect dust...Other than the display board,
it works great...It's easier to use when driving than the 706,
cuz it has no menus...I can work nearly everything on it, just
by feel...MK

Hi Thomas,

Thanx, your two bits were worth more than the academic plug nickel.
This is something that our original poster should hearken to as his
needs were obviously production oriented. Bench experience will trump
cut-and-paste theory in a heart-beat.

However, triple stub is pretty aggressive. How long did it take you
to flatten response?

I'll bet he used the air conditioner in the winter time in that car :)

and I thought I was crazy with my mobile setup. Years ago I had two hustler MO mounts each with the three way spider for 80-10 meters. I had two 2- meter antennas and two 70 cm antennas on the car in addition to the am/fm broadcast antenna on the car. It was nick-named 'The Porcupine'. Going to Charleston one day I had a console of radios surrounding me. The IC-730, Kenwood TS-440SAT, a dual-band 2 meter/70 cm radio and one each of two meters and 70 cm rigs. I haven't established my antennas yet on my current car, but the IC-706 MKII replaces most of the above. I'll be looking for a good dual band for the car for FM to go with the 706. Then I can operate HF while listening to V/UHF and visa versa.

made a 1/4 wave vertical (on the ground) for 40 m. (40 radials 1/4 wave)
and made a dipole at abt 45 feet high for 40 m.

I live on the countryside and my vertical is abt 15 feet from my house and
all other sides are clear.

The dipole is in 99.9 % better then the vertical in 99.9 %. A few times the
same. The dipole is abt 25 feet above the house and all other houses in the
village.

I only listened e.g. yesterday a YB station was 5-8/9 on the dipole and the
vertical was 4-6 with a lot of noise.

I am a fan for verticals but that the dipole worked so good I did not expect
that.

Did U.

Note that without adjustment, modern, solid-state FM broadcast transmitters can (and do) provide 80% or better PA efficiency into a 50 ohm load across 20% bandwidth, with no tank circuit or other in-band filter(s).

If this is done in a commercial service, certainly it could be done in amateur radio devices. Physics is not application-selective.

Posters of various forms of "Absolute Truths" to the contrary might well do a bit more research.

Cecil, W6DXP wrote:
"Well, it was re-enacted on the Discovery Channel."

There were no mountains around the medium-wave broadcast plants where I worked, but I can testify that atmospheric electrical activity there often started well in advance of the storm arrival while the sky overhead was still blue. Notably, tower guy insulators flashed over repeatedly. Transmitter overloads tripped the transmitters off the air for an instant to clear r-f arcs which followed the arc paths created by the static discharges.

Bolts do come out of the blue but do no damage in a well designed radio station.

Best regards, Richard Harrison, KB5WZI

The problem seems to be that the definition of TOA is
not standardized. Literally, TOA can be any angle but
has a special meaning when quoting EZNEC. Neither my
antenna books nor "The IEEE Dictionary" define TOA.
I did a search for "take off angle" and "TOA" on my
ARRL Antenna Book CD with zero results.

Response is flattened through gain controlling the pre-amp from a look-up
table held in the micro's EEPROM. The alignment procedure is automated using
the HB-IP bus from the spectrum analyzer and a computer. The
computer/analyzer also looks for harmonic content and spurious emissions
during this procedure. Think it takes about ten seconds to do this.

I doubt you understand what he wrote. I can't fathom why you would be concerned
with the OP when your own difficulties are so acute.

> Bench experience will trump
> cut-and-paste theory in a heart-beat.

How would you know?

> However, triple stub is pretty aggressive. How long did it take you
> to flatten response?

How long will it take you to figure out that he wrote not a wisp of a word on
what the "output-Z" of the amplifier is? He did write that he determines how
the amp was loaded to acheive power, something I've been saying is the prime
concern.

On another band, at a different distance, in another direction, at another time of day, the vertical will be better than the dipole.

Don't throw anything away until you have listened to several hundred stations, over a period of 6 months, at random times of day, on random bands, using the same receiver, and have performed a statistical analysis.

Richard Fry wrote:
"Physics is not application-selsctive."

True. The laws of physics are inviolable.

The FM amplifier does not need linearity. Amplitude distortion is irrevelant. Severe clipping to remove amplitude variations is common practice. Phase/frequency shift is the modulation of interest.

Clipping generates harmonics and FCC rules limit harmonic transmission in all services. Any manufacturer wants to require the fewest user adjustments. I`m not surprised that tuned frequency selective circuits are minimized.

I would be surprised if some final filter were not used to guarantee compliance with the rules.

Best regards, Richard Harrison, KB5WZI

Exactly.
After all there is some gain at 0 degrees, very small of course,
but would anybody consider that as the TOA.?
It appears that many consider TOA of little importance, but just consider
a antenna with a single feed point such as a big yagi for 20m with say
a 60 foot boom. Even with the high gain its TOA is in the region of 13
degrees
where smaller boom antennas will be about 14 degrees.
Now say we have another antenna with a single feed that has a TOA of
10 degrees with the same gain as the big yagi !.
Which antenna will OPEN the band ? They do NOT open at the same time
even tho they have the same gain so where Reg states that no amount of
changing or shaking the antennas is going to make a scrap of difference to
the" hop" distance is patently incorrect.
As an aside losses in a signal is directly related to the number of hops
that it takes
one hop less to communicate means a louder signal.
You can design a single feed antenna with a TOA of +/- 25 percent
from the norm which makes a terrific distance to the "hop " distance,
especially
if the lower contour of the main lobe is below the competition, as the lobe
will
be noticable thinner with a low TOA. You can ,ofcourse, lower the take off
angle
by using multiple antenna feeds ie stacking but that is another matter of
discussion.
Regards
Art

No the triple stub tuners are only for development. Production boards have discrete components to form the match network. Power levelling or "flattening the response" is computer adjusting the output power to compensate for the reactive components to ensure a constant output power over the entire band of the radio. We also put in a small temperature compensation coefficient into the EEPROM because the PA tends to put out more power when it is cold.

Hi Art,

Simply using EZNEC's freely available yagi design, I can come up with
a 11.4 dBi figure at 10 degrees. Can you say we have another antenna
with a single feed that has a TOA of 10 degrees with more gain that
this?

Hi Richard,

Yes, that would be the technical marvel of the ages, but just like our
rigs, even the biggest FM transmitters bend to the necessity for
output filtering:
http://www.broadcast.harris.com/product_portfolio/prod_media/Z%2DCD%20Bro%2DB.pdf

There is an amusing claim, however, for their power module(s)
"Each module is conservatively rated to produce
850W of power into a system VSWR of 1.5:11."

Not a very good copy editing job is my guess.

Looking at the "efficiency" side of the equation is simple here too:
>Power Consumption (nominal)
>ï¿½ Z2CD: 4.0kW at 2.2kW output power
55%
>ï¿½ Z3.5CD: 6.1kW at 3.75kW output power

Richard was asking how long it took you to tune the triple stub filters
during devolpment.

I am curious about the exact nature of the impedance transmformation
these devices provided.

Not so. You confuse receivers with transmitters. Limiting is supplied by the IF strips of FM receivers to reduce/remove AM components on the incoming wave, but FM broadcast transmitters are operated well below any limiting/clipping level, and that is probably true of ham FM txs also.

Synchronous and asynchcronous AM are low in broadcast FM tx RF stages (the FCC spec is -50dBc), but not because the FM amplifiers are "clipping." Broadcast FM txs easily can be adjusted over an output power range of ~25% to 105% or more simply by adjusting drive to the PA (keeping constant PA volts). This technique often is used for output power control/VSWR foldback, actually.

> Clipping generates harmonics and FCC rules limit harmonic
> transmission in all services. .. I would be surprised if some
> final filter were not used to guarantee compliance with the rules.

You are confused again. I wrote that no "tank circuit or in-band filter(s)" were necessary to achieve the high efficiency I described. Your post I was responding to states that a "tank circuit and other filters" are necessary for high efficiency -- that is not true.

Harmonics are present at the PA output of an FM transmitter, but "clipping" is not the process whereby they are generated, as I state above. They are reduced to legal values using a lowpass/harmonic filter. The FCC attenuation spec for harmonics and spurs more than 600kHz from Fc is 80dB below the unmodulated carrier.

The lowpass/harmonic filter does not improve efficiency--it has a small amount of insertion loss in the FM band.

Hi gwhite,

I would have to agree with you on most everything you have said through this thread. I once saw my boss (with his "PHD") try to model and match a power amp based on the small signal parameters off the datasheet. He insisted that the stated input and output impedances were characteristic parasitics of that amp and wouldn't change between a small or large signal. It was kind of pathetic to watch him struggle for over a month on the matching network, and I think he had resorted to guessing in the end.

I've often questioned why manufactures put small signal parameters on their datasheets? Makes no sense to me. Even if they do publish some large signal parameters it is unlikely to be the exact same mode of operation that you need for your project.

Playing with triple stub tuners on PA's has shown me that there are many combinations of input and output impedances that appear to give similar results at any one frequency, but give different results at others frequencies. So it's a matter of finding the input and output impedance that give you adequate performance over the entire scope of your project.

I don't think there would be a problem in beating that!
I would expect many could come up with one better than that at a feed
point height
of 1 wave length. Isn't the max gain theoretical obtainable just short of
16dbi ?
Allow for 0.5 db max losses seems like > 15.5 dbi is obtainable.
(using perfect flat terrain ofcourse with a 60 foot boom 'big' yagi)
With all the experts that reside on this group plus a zillion of antenna
reference books
I expect many to come up with antennas better than that.
Isn';t all now known about antennas and placed in print? (Grin)
It just needs is a bit of research or an expert to share his knowledge
with civility.

Another case of writing without knowing, I see.

The power consumptions you cite are the TOTAL values for those transmitters, not of the RF power amplifiers alone. The total value includes the exciter, driver(s), power supply losses, control circuits, and RF combining losses, as well as power for the internal cooling fans. The PA modules have 80% or better efficiency, by themselves.

The reason I know is that I was the author of those specs.

If your amp has to operate over a wide frequency range it is not likely that you can flatten the response just with stubs. Stubs should be looked at as more single frequency devices than broadband networks. But you can use the stubs to plot out the appropriate impedance curve on the Smith Chart to ensure a flat response when you model in the discretes.

I usually just try to get the flatness of the response as close as possible and rely on a software calibration routine to flatten it off. Saves a lot of time.

It's my understanding that a triple stub tuner of the right length can reach anywhere on the Smith Chart where as a double stub can not.

Hi OM,

Yes, I do recall your claims that contradicted Mendenhall's explicit
efficiency computations. So I see no need to pursue undocumented
claims you offer. Unless you can supply specific references from
Harris about this 80% efficiency, then such comments remain as suspect
as before.

>The reason I know is that I was the author of those specs.

I am still wondering about the odd entry of:
"Each module is conservatively rated to produce
850W of power into a system VSWR of 1.5:11."

I notice you passed on discussion to this particular point of
accuracy. 11s can be explained by hitting 1 too many times, or 80 by
hitting an errant 0 too many. One of those things that escape the
notice of a spell-checker.

"There is an amusing claim, however, for their power module(s) "Each module is conservatively rated to produce 850W of power into a system VSWR of 1,5:11."
Not a very good copy editing job is my guess."

Richard must be right. I guess a finger was left too long on the no.1 key and nobody caught it in time.

I admire Gates` scheme of paralleling many relatively low powered amplifiers. If one fails, you can continue almost as if nothing happened. Very nice.

Best regards, Richard Harrison, KB5WZI

Judging by newsgroup postings, I'd say the most common meaning of "takeoff angle" is "that elevation angle at which an antenna radiates". For this to have any meaning, it's necessary to assume that the antenna radiates at only one angle and no others. Since this is a false assumption, the term "takeoff angle" as used by most amateurs is meaningless. I've never seen the term in any non-amateur publication -- it seems to be in the same category as "capture area" and "S unit", creations which only amateurs seem to have a need for.

As you say, it has a precise definition as used in EZNEC. The first versions of ELNEC, incidentally, didn't report "takeoff angle" because I thought it to be unnecessary to point out what anyone can see from a glance at the pattern, and felt that the term would be misunderstood and misused. Turns out I was right -- it's misunderstood and misused, despite my best effort at explicitly defining it. But you've gotta give the customer what he wants, not what he needs.

> as suspect as before.

You may take what I wrote as being "from Harris," because I was part of Harris FM Product Management for those transmitters before my retirement in 1999 (after 19 years there). I was responsible for documenting all performance features and parameters published for the product line, using numbers generated and approved by Engineering.

If the PAs alone were as (in)efficient as you imply with your calculations, power consumption for the entire transmitter would be considerably higher. Common sense should tell you that PA module efficiency would have to be much higher than the efficiency calculations you posted in order for total power consumption to be as stated on the Harris spec sheets.

> I am still wondering about the odd entry of:
> "Each module is conservatively rated to produce
> 850W of power into a system VSWR of 1.5:11."

Yes, that is a "typo," as you noted. Very good. It should read "...VSWR of 1.5:1."

Richard Fry wrote:
"Not so. You confuse receivers and transmitters."

FM transmitters often use Class C amplifiers and frequency multipliers on the modulated signal. An AM signal can not be amplified by a Class C amplifier because of severe distortion of the modulated signal. In FM, amplitude distortion is irrelevant no matter where it occurs, receiver or transmitter. The recovered audio will sound just fine. It`s one of the many advantages of FM.

The question seems to be: If an FM transmitter's output signal
is not a reasonably pure sine wave, is a low-pass filter used
between the transmitter and antenna to reduce the harmonics?

3367. Antenna Encased in PVC

Newsgroup: rec.radio.amateur.antenna
Date: 2005-03-04 20:11:07 UTC
From: JE <Zeke@legs.com>
Message-ID: <vh3Wd.5900$DW.3875@newssvr17.news.prodigy.com>
Source record: 81105

I built a "J" pole out of 300 ohm inlead wire and have it trimmed where at 147.210 I have a SWR of 1.6 and on the low end at around 145.390 I have 1.2.

To protect it, I put in a 1" PVC pipe and now the SWR is way off the scale. Is it a bad idea to encase it in PVC or can I trim it down to get a better reading?

Thanks

Assuming your PVC is non-conducting, it may be changing the
velocity factor. Trimming would be the way to go.

I believe that many commercial antennas are enclosed in
PVC. Assuming your PVC is non-conductive, it is simply
lowering the velocity factor of your antenna (assuming
you haven't turned it into a fractal by stuffing from
one end :-). Try trimming it. If you ruin it, build
another. Or just build yourself a J-Pole from copper
tubing.

Don't professionals use the term? Seems like it shows up in pro computor
programs.
Doesn't the Antenna handbook refer to TOA ? I do know they made a graph of
incoming
RF ray angles which amounts to the same thing. What is wrong with the common
perception
that it is the angle of maximum gain?
If you were designing a 'point to point' antenna would you not look for the
angle of maximum gain?
If so what would you call that angle ? If you are refering to an antenna
lobe pattern could you not invoke
the +/- 3 db points as used in many other places in antenna work?
Methinks that people are looking for problems to argue about

Richard Fry wrote:
"Note that without adjustment, modern solid-state FM broadcast transmitters can (and do) provide 80% or better PA efficiency into a 50 ohm load across 20% bandwidth, with no tank circuit or other in-band filter(s)."

Well, Richard Fry didn`t say there were no out-of-band filters or traps.

One could have a low-pass filter that cut-off above 108 MHz, but below 176 MHz, and no harmonic would get through the filter.

80% or better efficiency isn`t coming from a Class A amplifier, so maybe it comes from a Class B amplifier.

One fly in the ointment is found on page 354 of Terman`s 1955 edition:
"The theoretical maximum possible plate efficiency that can be realized in a Class B amplifier is pi/4 or 78.5 per cent;---."

Best regards, Richard Harrison, KB5WZI

It may sound just fine to you, but carefully made performance measurements of a received FM signal having high AM show otherwise. AM on FM is far from irrelevant.

Yes. This question was answered in my post in this thread of 00:24UTC today, which I will paste below:

"Harmonics are present at the PA output of an FM transmitter, but "clipping" is not the process whereby they are generated, as I state above. They are reduced to legal values using a lowpass/harmonic filter. The FCC attenuation spec for harmonics and spurs more than 600kHz from Fc is 80dB below the unmodulated carrier.

The lowpass/harmonic filter does not improve efficiency--it has a small amount of insertion loss in the FM band."

Hi OM,

It is tedious to have to carry your water for you. I had to chase
down your Mendenhall references, this seems to be a consistent trait.
Claims are generous in this group and heavily discounted due to the
paucity of facts. Such facts as may be drawn out, but could have had
been as easily offered by you:

"For even greater reliability, any
PA module can be used as an IPA module,
with absolutely no modification."

It is quite obvious that as an IPA, that in the lower wattage systems
it represents overkill at 845W to generate drive to final PAs to 2.2
KW output. Hence the lower total efficiency.

On the other hand, an IPA driving 845W to generate 22KW obviously
makes better efficiency sense and is found in the overall 64.5%
figure.

NOW, if the PA finals, accounting for 22KW are 80% efficient, that
must mean that they only consume 27.5KW of power to do so, and that
with a power input rating of 31KW then leaves the IPA (an identical
80% efficiency module) and control circuitry to absorb 3.5KW to
deliver the drive of .845KW.

It follows that for an 80% efficient IPA, it accounts for 1KW power
consumption. This remainder is easily attributable to power supply
losses (if we simply assign an industrial average efficiency of 95%
for power conversion) otherwise the system TTL circuits and LCD meters
suck down 2.5KW on their own.

This, as you put it (but fail to evidence), would quickly subdue
suspicion. And an equal treatment to more conventional, retail
Amateur Radio Transmitters also reveals efficiencies through the same
exercise. It is quite evident that such transmitters are no where

near these vaunted examples - but few dare venture into these dissections.

No fly to those who really know this subject. They are neither Class A or B.

Those wanting to comment on modern solid-state VHF amplifier designs and performance parameters really should research them before doing so.

We are 60 years beyond the date of this citation from Terman.

They might be of some use for specific cases. For example, if the PA is class A, is used well backed off because of high PEP-to-avg ratios of the signal, and you've managed to get the output load dialed in, s-params can be useful for a first cut at the amplifier *input* match. I've always still had to do some tweeking though. Also, with some work and considering the load-line match, they can give you an idea of what gain can be accomplished. This might already be in the data sheet though, as you mention.

> Even if they do publish some large signal

One of the large signal parameters I like best is how much power the device can dissipate. ;-) Voltage breakdowns and Imax are nice too. ;-) ;-)

Yet another case where you write with guesswork, not knowing the facts.

Obviously you do not understand the architecture of this line of transmitters, even though what I am about to write is available on the Harris website. The PA and IPA modules are the same, and consist of two, independent amps--each amp capable of 425W output. Their actual output power depends on the tx they are installed in, and the power level required from it. The only thing they have in common is a heat sink. An IPA at any power level uses only one of these amps per 5kW (or less) block of PA amps. The other amp of the IPA remains unpowered and in reserve, and autoswitches on line if the active one fails.

The lower AC input to RF output efficiency of the lower powered transmitters arises from the fixed overhead in all units for losses OTHER than in the RF amplifiers, i.e., power supply losses, exciter and controller power, RF combiner and harmonic filter losses, and cooling power--the AC consumption for which in low power units is a larger proportion of the total.

Look in the ARRL antenna handbook for "shunt feeding".
That is appx the same as a gamma match, etc.. Many
feed towers this way. IE: you drop a parallel wire down
from a certain point on the tower or mast, and usually is
combined with a capacitor. Directive elements don't
work too well with verticals. Better to feed as phased
arrays. MK

Oh, and going from 8 ohms output impedance to 10e-7 (unless I
miscounted) would take the damping factor from 1 to 8e7, which is a bit
more than 2. Ignoring the speaker wires of course.

Hi OM,

How amusing. :-)

>Obviously you do not understand the architecture of this line of
>transmitters, even though what I am about to write is available on the
>Harris website.

Yes it is, isn't it. What that has to do with MY intimate knowledge
of them is hardly the point when I asked YOU for details. But this
posting only gets better.

>The PA and IPA modules are the same,

As already noted in my direct quote above.

>and consist of two, independent amps--each amp capable of 425W output.

Not being particularly knowledgeable, and taking your advice about the
information's availability (seeing that I provided the link, not you):
"Each module is conservatively rated to produce
850W of power into a system VSWR of 1.5:11"

AH! there we are with that errant SWR again. I wonder how you
explained that without noting this other egregious error of 850W?
What is even more amusing is that either way (425/850) it has
absolutely no impact on the outcome. But this gets better, after the
snooze that follows:

>Their actual output
>power depends on the tx they are installed in, and the power level required
>from it. The only thing they have in common is a heat sink. An IPA at any

>power level uses only one of these amps per 5kW (or less) block of PA amps.

How boringly trivial. Does the recitation of irrelevant facts bear
on some point being drawn here?

>The other amp of the IPA remains unpowered and in reserve, and autoswitches
>on line if the active one fails.

Op. Cit.

>The lower AC input to RF output efficiency of the lower powered transmitters

I said as much in the top section. However, if you enjoy your own
words that's fine, but it is becoming repetitive barring any obvious
point. (Both my and your entry could have as easily been left out -
did you say you were an editor?)

And so it is when operating as a PA output module, when both sides of the module are active. In IPA service only one side is active. The words on the website say so.

> Let's see, I have offered an analysis that supports your thesis that
> the efficiency of this transmitters elements are ballpark 80% and you
> say I am WRONG? What a hoot!

Only by an absurd conclusion that to get there "the IPA (an identical 80% efficiency module) and control circuitry to absorb 3.5KW to deliver the drive of .845KW." Note also your incorrect value for IPA output power. It is never more than 425W per 5kW (or less) block of PAs. If more PAs are used in that power level tx, another IPA and PA block are added. Of course, you would know that if you took the time to read and absorb the website data.

> I can only wonder why you can't offer your own numbers to show my
> error. :-) I originally wondered why you couldn't offer your own
> numbers and carry your own water. Go figure....

Honestly, given your penchant to ridicule and intimidate people in this newsgroup, I have little motivation to carry your water. There is much data about these txs on the Harris website, free for the reading. I am through trying to set you straight.

It is incredible how you, as someone with barely a perfunctory understanding of this transmitter system, feels qualified to argue about it here with someone who has been part of its development team. "Go figure..."

Message-ID: <m-3252F8.22274104032005@news.verizon.net>
Source record: 81031

well today i finished putting my dipole up

it's a center fed 25ft hot side 40ft approx rfgnd side.

at the base of a mast (5ft) i have a sgc237 tuner feeding 5ft of
450ladder (to the dipole)

with lmr400 (150ft run) one for hf one for 2/440 and one 8conductor
18ga control ccable for tuner

unfortunately i am about 4-5ft away from the building master
antenna--had no choice here

I did put a pro tvi filter just before the master tv ant amp by ice

Seems using about 20watt i can tx from 160-6m w/o any problem w/ 2
exceptions i noticed on a quick test

**1) i have 2 tvs a 'good' sony and a old toshiba , on 20m cheep
set will loose a little color when i tx it kinda makes bright red
for ex. into a dull red (all colors).

using a set side radio shack tv filter(back of tv) didn't help seems
to barley effect 4-11 but 2 and 13 are most effected on my cheep set

this practically had no effect on the 'good'sony

note: i have good grounds and lightning protectors inline and on my
rig, (both rig side) .. i also have a w2du balun near the sgc237 and i
also tried a drake tvi filter by my rig guess it's the 54mhz cut off
kind (didn't help)

***2 on ten meters I whipe out ch2 herring bone fuzz both sets
again filters set side didn't help

I also tried a drake hf tvi filter on my rig no effect

it's a bit strange i seem ok on 6m thought for certain i'd blow there
but we all know 10m can also cauz a bit of tvi

question:
anyone have any ideas how i might be able to reduce/elim the prob on 20
as it seems small,, and perhaps someone smarter than i might also have
a few tips for clearing up 10m

i guess having most bands but two isn't bad,

thanks all

m

I hope this, from an old antenna book, is relevant in finding
something called "vertical lobing".

It has:
(for a 1/2 wave vertical dipole, I gather)

N = Height in ft. x Frequency in Mc

984

where the number N is number of wavelengths. It locates the angle
above ground at which the 1st maximum lobe is transmitted.

then using this approximation gets the maximum signal at:
tan (theta) = H/D

and the zero signal:
sin (theta) = 1/2N

where H is the height above "flat" earth of the receiving antenna
and D is the path length (in the same units)

when H/D = 1/(4N) a 1st maximum lobe is attained at the receiving
antenna.

There's more for the actual height at the receiving location and other
lobes, nulls, etc...

A*s*i*m*o*v

... And some fell upon stony ground and had no THC at all.

Did you order DB224-A (150-160MHz) or 224-E (140-150MHz) range models? The harnesses on the antennas are for their proper range....the harness between the two antennas can be easily made up of 75 ohm RG11 coax cut in ODD multiples of 1/4wavelength (taking Velocity Factor into account!). The lengths would be the same on each side of the T to the 224 feedpoints. Easy to do....the harnesses on the antennas are made to match 100ohm elements down to a single 50 ohm point.....but as long as both antennas are the same range, you only need to worry about the harness between the separate 224s

aunwin@insightbb.com wrote:
> Don't professionals use the term?

I don't believe so.

Seems like it shows up in pro computor
> programs.

Yes, it's a carryover from the amateur programs. Brian Beezley, K6STI was, I believe, the first to use it in an antenna analysis program. (You won't find it in NEC-2, NEC-4, or even MININEC.) Those of us who followed were pretty much forced to include it because of demand from the amateur customers. I can't speak for other programs, but it's in EZNEC pro simply to keep the amateur and pro programs similar.

> Doesn't the Antenna handbook refer to TOA ? I do know they made a graph of
> incoming
> RF ray angles which amounts to the same thing.

The ARRL Antenna Book probably uses TOA. It's a publication intended for amateurs. No, a graph of incoming ray angles is not a graph of TOA as used by EZNEC and other programs. You've just given a good example of the misunderstanding and confusion that the term is subject to.

What is wrong with the common
> perception
> that it is the angle of maximum gain?

Nothing at all. It's just that a lot of people think it means something else. In some of your postings, in fact, I get the sense that you don't always use it with that meaning. For example, you sometimes seem to give a lot of weight to the TOA as a figure of merit, and none at all to the field strength or gain at the angle at which communication is taking place. So either you're using TOA in a different sense, or you have no interest in maximizing the ability of an antenna to communicate effectively.

> If you were designing a 'point to point' antenna would you not look for the
> angle of maximum gain?

No, and there's an example of the perception problem. If you don't understand why, please go back and re-read posts I've made in response to your earlier postings on the topic.

> If so what would you call that angle ?

In EZNEC, the term takeoff angle means exactly that. My well-confirmed fear is that people would use it as you seem to be doing.

If you are refering to an antenna
> lobe pattern could you not invoke
> the +/- 3 db points as used in many other places in antenna work?

Lobe pattern? Invoke? Sorry, I have no idea what you're asking.

> Methinks that people are looking for problems to argue about

Also ignoring the ***voice-coil resistance***. If that is included, as
it must be for a correct analysis, you get 2.

F Langford-Smith 'invented' the concept of damping factor, and around
1949 accepted the point made by James Moir that, by not properly taking
into account the effect of the voice-coil resistance, it was a seriously
misleading concept. Yes, 60 years later, people are still being misled.

Hi,

i've been trying to get WinScanner or WinTransceiver from Malzev for the
resident Jackson: Winjack.exe,
and also for the Icom IC-240: ic240.exe.

I found all I need at a TriPod hosted site:
http://members.tripod.com/~Malzev/cb-adio/jackson.htm
http://members.tripod.com/~Malzev/cb-funk/ic-240.htm

The llinks to the needed executables are:
http://members.tripod.com/~Malzev/radiodoc/software/ic-240.exe
and
http://members.tripod.com/~Malzev/radiodoc/software/winjack.exe

But Tripod blocks the download of executables.
Anyone knows how to get a hold of this software?

tnx...Marco

HI Gil ,
From a purely signal perspective. it would make no difference if it
were fed at the end or in the middle. However from a matching
perspective the center fed arrangement will give you the easiest
matching situation for the tuner to handle and less chance of unwanted
R.F. in the Shack. I'd go for the center fed if possible. if not the
endfed will work but may present you with matching problems on some
bands. also you could allow extra wire to drop down vertically from the
end in the center fed arrangement giving you a better match 80 or 40
Meters if desired. Make the total lenght about 88 feet and you'll have
a good all band antenna. that would be 25 feet horizontal on each leg
and 19ft dropped veritcally.
Remember though any wire is better than no wire.

I just started to wonder something

always thought it was 'ok' to have a center fed dipole equal length arms
if that is your goal

many have mentioned that using my sgc237 it's better to have the rf
hot shorter then the rf gnd/counterpoise

got confused here why is that better, i mean understand many have
said it prevents the rf gnd from radiating the coax shield (bad)

but what is the diff thing i am mising?

tnx

As a rule I subscribe to the school that says every antenna should be
well-matched, in the clear and fed with low loss line, even those used
for receiving. Must come from my VHF/DXing background.

That said, I know my friend Roy is correct and I am wrong when he
gives this advice. Generally speaking, the SNR is set at the antenna
and nothing done after that will make much difference. This isn't
always the case if there are noise sources that can nulled or reduced
by phasing or other directive techniques that don't reduce the signal
simultaneously.

Roy did not mention this at all. He spoke to "impedance matching."

Wes N7WS

ps. You have no idea how hard it is to type with one (the "wrong")
hand while doing drugs. I had 2 1/2 hours of surgery putting my rt.
shoulder together on Thursday. Just in time to keep me out of the DX
contest---good planning :(

Good point. I stand corrected.

The only nit I would pick would be that impedance be used, since you
need to measure it at the frequency(ies) in question, not DC. And then
there is that pesky crossover in most systems. Personally I like biamping.

Roy,
by now you must know that I experiment a lot using computor models
and actual building. I built a 80 meter boom yagi which was neat because
the underside of the first lobe captured a lot of signals as the band is
opening. So was the next step to make even a longer boom yagi to drive
the underside of the lobe lower, no ....because I am now too old and weaker.
So I now pursue the object of a lower take of angle by using more elements
with more coupling and one that can rotate in a circle equivalent to a
two element beam. I believe this can be accomplished with the same gain
and a lower take off angle than a 60 foot boom yagi. Thus TOA becomes
the most important thing for me as well as the "thickness" of the lobe.
That is the sense that your response questioned regarding my maximisation of
antenna
performance for which I use TOA.

Best regards
Art

==========

Cecil, it's worse than that. TOA is almost meaningless.

Whoever coined the phrase "Take Off Angle" in conjunction with Eznec-type radiation patterns should be made to provide a 5000-word written explanation before he went to bed on his wedding night. Another form of safe sex?

In the first place, your suggestion to hire a helicopter to fly around the sky in the vicinity of an antenna to determine the TOA would provide a completely different TOA from that provided by Eznec. Especially at low angles, say less than 30 degrees.

That's because the angle at which radiation is strongest in the vicinity of a vertical antenna, of height 5/8-wavelength or shorter, is ALWAYS at an angle of ZERO degrees. ie., it is strongest along the ground surface regardless of soil conditions. Distance from the antenna is too short for the ground wave to be appreciably attenuated.

Somehow or other, Eznec manages to calculate relative field strength at some great distance from the antenna. Which is, of course, an ultimate worthwhile but unobtainable objective.

Unfortunately, Eznec ignores what that distance may be, whether the receiver is at ground level or at aircraft height, or in the stratosphere. In the extreme state of uncertainty it ignores the height of the ionospheric reflecting layer and the number of hops. In other words, if the location of the receiving antenna in space or time of day are unknown then the Eznec TOA is meaningless.

So why is so much importance or significance attached to an Eznec TOA? It is merely one of the infinite number of angles contained in a very broad lobe of a radiation pattern.

The path actually taken by a particular radio wave is of far greater importance. And knowing the location on the Earth's surface of both transmitting and receiving antennas, the path taken, including elevation angle, is calculable purely by geometric means. It has nothing to do with the antenna, not even a G5RV.

If the ballpark Eznec TOA, by chance, happens to crudely coincide with the actual radio path angle to a distant receiver then that's the best which can be expected. If not, then there's nothing you can do about it except change

the antenna, all the soil in your back yard, or your geograhical location.

Save yourself the going-rate per hour of the fee for hiring a helicopter.
;o)

By the way, this assessment of the situation in no way demeans the value and usefulness of Roy's Eznec - an excellent practical, educational and free-issue program. My only criticism is that it requres a 4-week course of self-instruction, two hours per day, to understand how to use it. But I suppose, starting from scratch, this is inevitable. I imagine that simply to point to Eznec in response to an elementary query on this newsgroup can often lead to a waste of time down-loading it, disappointment and frustration.

Reg, G4FGQ

Hi Art,

Back when fractal antennas ruled the sky - at least on paper - the
bragging rights were carefully tailored to fit the design.

Some of this was arguably targeted to a user population that would
have enjoyed the advantage. Anyway, such an example is shown at:
http://www.qsl.net/kb7qhc/antenna/fractal/n1ir/k2/index.htm

The fractal flyer, and its superior, simpler cousin the H Flyer showed
a real, improved, DX response at 10 degrees. This was not their best
response angle which you call TOA. In fact, both designers studiously
ignored what you call TOA because it was not particularly notable.

So, as a bald statement, both designs constitute very small antennas
that exhibit BETTER gain figures at a TOA of 10 degrees than a full
sized dipole held at a comparable height. Also, these antennas show a
F/B that is very much better than a full sized antenna. Further, both
designs, but notably the H Flyer, show full band matching. However,
having said that, sans actual response levels or context, is having
said nothing.

However, let's look at the full characteristics, not simply the
claims:

Best Response:
Std Dipole 0 dBi @ 90ï¿½
fractal flyer -0.81 dBi @ 39ï¿½
H Flyer -0.6 dBi @ 45ï¿½

10 Deg. Response:
Std Dipole -7.51 dBi
fractal flyer -4.85 dBi
H Flyer -4.75 dBi

2:1 Match Range:
Std Dipole 0.85 MHz

fractal flyer 0.5 MHz
H Flyer 1.0 MHz

As can be seen, the H Flyer was the best design across the board, IF you accepted the limitations originally imposed (very low, very small, and scrutinized at 10 degree take off). Does this qualify it as a good antenna? Depends on if you are space and height limited.

One last point, as poor as a valuation of -5dBi is, there are very few designs (barring the two shown here) that can perform better and still fit in the box.

So, let's return to claims, especially for the H Flyer:
Smallest resonant antenna;
Highest DX Gain;
Widest Bandwidth:
Best F/B;
Not a Fractal.

Hi Myles,

I didn't see that/those particular posting(s), but I cannot imagine
that being an issue.

>got confused here why is that better, i mean understand many have
>said it prevents the rf gnd from radiating the coax shield (bad)

Sounds like bum advice. However, to snub radiating currents on the
coax shield you use a choke. The choke can be either with ferrites or
air winding the coax itself. This was discussed previously in this
forum, consult the archive with a search against your postings:
http://groups-beta.google.com/group/rec.radio.amateur.antenna?hl=en&lr=&ie=UTF-8
to get your bearings, and:
http://groups-beta.google.com/advanced_search?q=&hl=en&lr=&ie=UTF-8&
to perform a specific search.

I notice from another posting, you report mixed results about
interfering with TV reception. This can come from a mix of possible
problems, again, all this has been discussed in previous postings of
your threads. One thing I see missing in your description of your new
antenna is confirmation that you have also choked the control lines to
your SGC 237. If not, do it.

Oh my, that's gotta hurt.

Some years ago my wife had hand surgery and afterwards was getting
physical therapy. Another patient there had lost a thumb to a
circular saw. They made him a new one out of another finger.

That may be true in the Danelaw where you live, Reg, but not in the
rest of the universe. Imagine a circuit consisting of a voltage source
in series with a source resistance followed by a shunt capacitance in
parallel with a load resistor. Write the output voltage equation for this
circuit. Now, replace the source resistance with a short. Write the
output equation for _this_ circuit. Compare the two equations.
Are the frequency responses the same? Now use an indeterminate
impedance for the source resistance. Can you tell what the voltage output
of this circuit is?

I wonder abt antenna high. How do we count the antenna high? Is it referenced from the ground, or the roof of a building. Say I put a 3 el yagi on a mast connected to my roof, apx 5 meters above ground. Does this distance from the roof to the ground count, or do I have to put it up another 1/2 wave from the roof top ? Any experience?

Regards
Ken

Do you mean "height" ?

If so, it's height above ground that counts for propagation purposes. However it would also be important to site the antenna well above the roof as well to avoid interaction from the roof - all height helps !

I assume you are putting up a 10 metre 3 ele beam ?

Many thanks to all who commented on my initial "antenna philosophy" article.

Looks as though the time is coming when my antenna no longer will be philosophical but will be REAL. After some tribulations, we signed a contract to purchase a lot on the Mississippi Gulf Coast (where we are now living in an apartment). We are now wrestling with a floor plan and should break ground in mid-April.

The lot is covered with 70-foot-plus pine trees, all of which will be cleared -- you don't want them anywhere near the house because they tend to fall over in hurricanes. However, along the back edge of the lot are three slender oak trees -- 40 to 50 feet tall -- and before I could say anything, my XYL announced that we had to keep the oak trees so I could hang antennas!!!

The two most distant oak trees are 85 feet apart so now I'll need to sort out a multi-band dipole with 85 feet of horizontal -- guess I could use 135 feet and hang 25 feet vertically or sloping off each end.

Stay tuned.

Not a bad idea actually. But how do I tell where the gnaw point is? These tree rats are like dogs, they do it when and where they want to.

So how many years of *not* having blown down in hurricanes does it
take to grow a 70' pine tree?

I'm likely way off base here and just don't understand Mississippi but
I'm reminded of some of my neighbors who buy an acre or two of the
most beautiful desert on the planet and blade it to bare ground
because they don't like cactus. Or those who move here from somewhere
else and complain that it's too hot, it doesn't rain enough, it's too
brown, there aren't enough trees, traffic is awful, schools are
overcrowded and there are no good paying jobs.

Sorry if I offend, I just can't help myself.

You are speaking truth. I've read about the thousands of easterners and
Worst Coasters who moved to the Arizona desert for their health, insisted on
planting the same trees and plants that created their allergies back "home"
and ruined the air in their new home too.

Pine trees grow like weeds here. A 70-foot pine tree is likely 20 or so years old. And, the problem is not just the hurricanes, it's the near-hurricanes. Every one of these trees has limbs that were ripped off and several of them have tops that were blown out over the past 20 years or so. Most of these are tall and straight enough to produce lumber so the guy who is clearing the lot is not charging anything as he will sell the logs, which will more than cover his cost to clear.

We are leaving the low trees and shrubs -- live oaks, bay, coast myrtle, etc.

Would be nice if someone invents a "X-Ray" like device that lets one to see the radiation pattern emanating from an antenna. That would make it so much easier to see how your antenna works, wouldn't it?

Is it only my dream or such device really exists?

The older they get the easier they fall. We got some 100+ foot white fir trees here that come down at only 40-50 MPH winds. Douglas firs and redwoods normally take a little more wind. Believe me when one of the babies (weighing several tons) come down right next to you house you'll think quite differently. That's why I cleared them out from around my house.

While clearing the pines I hope you are clearing out all the trees near your
house. One of the home repair shows stated that if you have a bunch of
trees around and remove most of them the ones that are left will blow over
easy. Seems they are depending on each other to help shield the wind. If a
tree is out by its self then it puts down more of a root system and will not
blow over as easy.

My father had ten acres of that kind of "Weeds" cut a while back.
The sale of the logs was enough to retire on for life! Nice of
the guy to not charge you for making him a small fortune!

Logs that size bring from $1,000 to $3,000 each!

3440. Re: How can I measure or observe my hf antenna's take off angle?

Newsgroup: rec.radio.amateur.antenna
Date: 2005-03-06 04:09:31 UTC
From: "J. Mc Laughlin" <jcm@power-net.net>
Message-ID: <112l0isnalegtee@corp.supernews.com>
Source record: 80978

An equation that I find useful when starting to think about a tradeoff between antenna height of a horizontally polarized antenna and performance is:

Beta-N = ArcSin(N * 74.948/H * F)

N is an integer. H is the height of a horizontal antenna above a flat, perfectly reflecting surface in meters. F is the frequency of operation in MHz. Beta-N is in degrees.

For N = 0, 2, 4, 6 ..., Beta-N is the angle above the horizon of a (theoretical) null.

For N = 1, 3, 5 ..., Beta-N is the angle above the horizon of a maximum.

I store this equation in my calculator and can solve for any of the variables. Thus: at 18 MHz, it takes a height of 32.2 meters to have the first null (above the horizon itself) at 15 degrees (N=2) - and, at the same height, the first peak (N=1) will be at 7.4 degrees.

Of course, the earth is not flat and is not perfectly reflecting (even for horizontally polarized waves) and so on ... However, this equation helps with a first cut.

[For those who use feet, the coefficient is 245.89 rather than 74.948.]

I really do not understand what you are getting at.
Your antennas are very small but are outside my interests.

I am looking for as long a hop that I can get on 20 meters
and ofcourse it must accept power.Beyond a 80 foot boom I am
constricted , thus I work backwards and start off with a smaller
antenna to which I apply changes in design to obtain the equivalent
of a 60 foot antenna based on the contour of the main lobe bottom.
(this includes changing the structure so that the gain and
front to back maximises at the same frequency
which is where the f/b is really meaningfull)

This is a long, long way from what you are describing and I might add that
my antenna design must be multi banded when I have attained the 60 foot boom
equivalency. Armed with this achievement I can now proceed to attacking
the
problem of exceeding the 60 foot boom yagi performance by using the now
freed
up land space

Can you re phrase your posting, possibly from a different direction, exacty
what
you are trying to add to this thread especially where it affects what I have
posted.

If you neglect giving us response levels, or context (like height,
length, frequency, ground conditions) then telling us you have a great
10 degree TOA is meaningless.

More to the matter of the thread, it you cannot tell us antenna
location and that location of the intended DX, and the height of the
skip layer, then a great 10 degree TOA could easily be useless.

If this is simply about bragging rights that knowing the DX location
is inconsequential because you will hit somebody, that could as easily
be said about a great 20 degree TOA antenna which makes the great 10
degree TOA antenna another face in the crowd.

Hello,

On 2m/70cm some antennas work better when you use a mag mount (Sirio HP2070 for example) because they are tuned to be used with a mag mount: added parasitic capacity between bottom of the mount and the car's steel. Expected you do not drive a 'vette or an Audi...

For lower frequencies it's better to drill holes or to properly ground the antenna to the car, as most mag mounts are not wider than a sq foot and you would quickly be annoyed by the potential differencies between the car's ground and the antenna ground, resulting in HF re-entry problems as your antenna will be then antenna + coax cable and all the hassles of bad and/or variable SWR.

dear rich thank you very much for your responce

I did use a w2du inline choke thing topside I didn't choke the
dataline comming from the tuner up there , my choke place was out of
those nice snap on's i'll get them soon

i do have the smartlock 'box' down to my house so it's not just 12v
going to it however i thought the choke was (on the tuner lines) was
only if say my rf made the tuner malfuction

I ran 18g 8 conductor down (thought some extra pair might come in handy)
of which the tuner uses 4wires the unused currently is just unconn both
ends.

can those control lines somehow get my rf in them and radiate?

rich what do you think of this I left a litte too much slack up to my
at, abut say 2ft didn't know what to do w/it, afraid to make a coil
I folded it back along the coax so it's like a long skinny ovel
--could this be causing my 20m slight interference (i'll presume my 10m
interf is expected)

thanks again

m

> >
> ========================

There are two typing errors in the above equation.

Beta-N does not mean Beta minus N.
It just means the N'th value of Beta.

And the intended equation should be -

Beta = ArcSin(74.948*N/H/F) degrees.

Alternatively,

Sin(Beta) = 74.948*N/H/F degrees.

That is, divide by F, NOT multiply by F.

I plan to use some of the trees at my QTH as a tower. I have to parallell trees that is apx 50'. At the top they will be abt 15'' thick. They are spaced 20'' which makes it easy to build a ladder so that I can climb up. I plan to build a metal plate and install a rotor on the top of the parallell trees, so that I can turn my 15' boom lengt 3 el 20m yagi beam. This tower would be very cost effective.

Of course I am aware of the potential problems regarding maintenance etc, but does anyone have experience with this kind of tower? Will it be stable, what abt guying etc. Comments is welcome before I settle this project.

Now I understand where you are coming from !.
I've given a lot of info out about the antenna
and its attributes, many of which are unique.
Also why I am following this path
I do not consider these posts mention of the attributes such as
feed point height or details regarding F/B as meaningless
and certainly not points about which to argue.
I did ask on another posting if there was anything written on a particular
subject regarding a particular feature but there was no response so there is
not a lot of interest in some aspects
If I have declared something that is impossible I would be happy to debate
it
but at this point I am not ready to publish all details which I am sure that
you
understand

Providing actual values should have resolved any latent ambiguity.
Nevertheless, I should have assumed the use of a TI calculator.

Beta-sub-N = ArcSin((N * 74.948)/(H * F))

The argument of the ArcSin is the product of N times the indicated
coefficient all divided by the product of the height times the frequency.

Height is in meters. Frequency is in MHz. N is an integer. Even values of
N apply to nulls. Odd values of N apply to peaks. Beta-sub-N is an angle
in degrees measured from the horizon towards the zenith.

The equation assumes an isotropic*, purely horizontally polarized antenna;
and a ground that is flat and has a reflection coefficient of minus-one for
an incident horizontally polarized wave independent of the
angle-of-incidence.

* Note: In this context, isotropic is to be understood to mean broadside
gain is constant and is independent of angle.

Fortunately, broadside to most horizontally antennas and for most
grounds, the conditions are close to being satisfied for Beta up to perhaps
30 degrees. The angles that are important for "DX," I have found to be
between two and twelve degrees. In other words, if long distance contacts
are desired, it is desirable to have most of an antenna's gain be between 2
and 12 degrees above the horizon.

Consider the person who places a 14.2 MHz Yagi at 60 meters (the magic
height above which one has to deal with the FAA). As a first approximation,
such an antenna is expected to have a peak at about 5 degrees and a null at
about 10 degrees. When the band opens, such a system is likely to dominate.
When propagation is better, those with lower antennas might have more gain
at the useful angle.

At last reason prevails.......
For DX purposes only the bottom half of the
main lobe is usefull. If your TOA is 13 to 14 degrees which is average
then more than 50 percent of the main lobe is serving no purpose.

If one wants to capture the highest possible number
of DX contacts then the TOA should be the angle where the
upper side of the main lobe is 3db down from the TOA.
Lower than this point renders the antenna useless as propagation sets in.
Mac shows this with a antenna having a TOA at 5 degrees that
has a theoretical NULL at 10 degrees which means 50 percent of
incoming signals are not available to the antenna user

Assuming you are talking about two parallel trees, not trees grown
together all the way up, I don't think you will have the results you
expect. The trees WILL sway towards and away from each other and
destroy any means of connecting them together. If you were to use one
tree, you might get away with mounting the antenna there.
Unfortunately on a windy day your antenna is subject to being whipped
to pieces as it not only gets hit with the wind at it's natural speed,
but also as the tree whips it back against the wind increasing the
wind load to as much as two to three times or more.

I have never mounted a beam in a tree, but I have mounted verticals at
the tops of trees. I have never had to go up and bring down one of
those verticals. Relative to some of the trees I used, you have a
short tree and if it's fat enough, it may not sway as much.

I would test your theory with an inexpensive or throw-away antenna
first before setting up your beam.

Good luck.

Remember a tree is living, unless you limb the tree and kill it. If
you do, then the tree will start to rot after a while. If you decide to keep
it alive, things will change as the tree continues to grow. Myself I would
prefer a tower, I have strung wire antennas from trees, that works well, IF
you maintain things.

I'll second the GE Super or the Sangean CCRadio. I also have a
Select-A-Tenna which I use with the portables and a hardwired TERK
version which I use with a Denon TU-800. Both work very well, but you
may need to buy a Lazy-Susan to get the best use of the portable radio
with the external loops mentioned.

CCrane is a great place to start looking.

Hi Art,

To that, all that info rarely comes in one post or even within the
scope of one thread.

>Also why I am following this path
>I do not consider these posts mention of the attributes such as
>feed point height or details regarding F/B as meaningless
>and certainly not points about which to argue.

No, no argument, simply put, it is needed information to base any
discussion upon. When it is lacking (and when only you can supply
it), then there is no point for discussion. You might want to
consider this in light of your next quoted line:
>I did ask on another posting if there was anything written on a particular
>subject regarding a particular feature but there was no response so there is
>not a lot of interest in some aspects

Okay, better understood now. As a novice woodworker, I would suggest
that you get a better deal on the timber than just having it removed
"for free." But maybe again I don't understand the economics of MS.

My 35' high Saguaro cacti are probably 150 years old so things work a
little slower here. (g)

I realize that we have to remove vegetation to plant our houses, I
just go ballistic when I see a developer clear cut an area to plant a
dozen California-style stuucoboxes on an acre, when by selective
cutting and building few-higher quality homes he could make just as
much money and cut down (sorry Danny) on the Californication of
Arizona.

3465. Re: How can I measure or observe my hf antenna's take off angle?

Newsgroup: rec.radio.amateur.antenna

Message-ID: <112mok4dr796o21@corp.supernews.com>
Source record: 81004

Needing a break from the exceedingly excruciating task of preparing income taxes, I took a break to investigate what EZNEC/4 has to say.

To facilitate checking and to use an antenna with more vertical pattern than that of a dipole, I used as an antenna the 14.2 MHz five-element Yagi provided with EZNEC. I looked at the first and second peak and the first null (above the horizon) for three types of ground. I also used three heights.

---We all know the uncertainties with estimates of the characteristics of ground, so let us not replay the issue.---

The conductivity in SI units and the relative dielectric constant immediately follow the height in meters. Angles are in degrees above horizon.

H = 22 meters
0.005 13
peak 12.5; null 28.3; second peak 41.6
0.01 14
peak 12.6; null 28.3; second peak 41.6
0.002 10
peak 12.5; null 28.4; second peak 41.6
Use of equation:
N = 1: 13.9; N = 2: 28.7; N= 3: 46.0

H = 33 meters
0.005 13
peak 8.7; null 18.5; second peak 27.8
0.01 14
peak 8.6; null 18.5; second peak 27.6
0.002 10
peak 8.6; null 18.6; second peak 27.7
Use of equation:
N=1: 9.2; N = 2: 18.7; N = 3: 28.7

H = 44 meters
0.005 13
peak 6.6; null 13.8; second peak 20.7
0.01 14
peak 6.7; null 13.8; second peak 20.7
0.002 10
peak 6.6; null 13.8; second peak 20.7
Use of equation:
N = 1: 6.9; N = 2: 13.9; N= 3: 21.1

One could conclude that the farther above ground one is and the smaller the relevant angles are, the better the fit with the equation. Think about why the first peak above real ground occurs at a smaller angle than what would be the case with a perfect ground.

As several have commented, what counts is to have gain at the angles to be used for propagation. The equation provides some useful information but it needs to be understood. No substitute exists for having a horizontally polarized antenna at heights that are appropriate for the task.

One extensive project that I worked on involved distances less than one hop. A significant issue was the desire to minimize gain at low angles where interference resided. Among other things, it was important to suppress vertical radiation as much as possible by choking the transmission lines and by having the wires be close to horizontal.

A point in engineering is to know/learn what the desired end results are and then to use tools that are to-hand to approximate the desired end results. In the case of HF systems, as many have observed, a statistical knowledge of propagation plays a large role.

Back to taxes. Any man-made system of such complexity is inherently inequitable.

73 Mac N8TT

P.S. For receiving purposes, combining a high antenna with an identical antenna about 0.5 WL lower can almost cancel the second lobe and thus attenuate much of the first hop (strong) QRM. Such a scheme does little for transmitting effectiveness. Compare the placement of the null using H= 33 with the second peak using H = 44.

This is not my thread which is about TOA. I did add a posting remarking about
TOA and you took on yourself to say it was meaningless. In your normal
fashion you took on laying a foundation for augument rather than
correcting the term to make it meaningfull.If you contribute to the thread by
giving the correct term for the angle of take off, then many would be
interested.
On the other hand I did initiate a post regarding max gain and F/b being on the
same frequency and the basis or logic that I drew upon to make that
statement.
You often take the aproach that all is known (or you know it all) and if there
is no written evidence pertaining to it then it is false and an augument
then follows.
Now that is you chance for you to wax and wane as to why that logic is faulty
which by being the author I would be duty bound to respond and defend my
statement .
All I do ask for is you keep your responses to the subject at hand and not to invoke
Shakespeare or the Doyle Carte company renderance of the Pirates of Penzance as proof
knoiweledge of your critique.

If one writes the equation, for elevation angles of nulls and maximums, in terms of free-space wavelength instead of frequency, an even more simple equation is obtained :

Beta = ArcSin(N * Lambda / 4 / Height) degrees.

Where Lambda is free-space wavelength
and Height is height above ground.

When N is odd, Beta corresponds to a maximum in the pattern.
When N is even, Beta correspnds to a null in the pattern.

OK Art,

This posting has been swinging in the wind for a couple of days now.
Given that you threw your frustration in my face that no one shows any
interest in it. Stop blaming them for their failure to recognize your
genius and get down from Calvary - blame me instead! ;-)

WTF do you mean by
> if one drew a polygon of element phases in a array
and WTF should we care?

Dear Reg:
Quite. I have found it more useful to use frequency.
73 Mac N8TT

P.S. The peaks and nulls suggested by the equation agree quite well when
compared to those resulting from using a "perfect" ground with EZNEC/4 as
long as the angles are less than about 30 degrees. In FS, the Yagi is down
1 db at 21.5 degrees and down 2 db at just under 30 degrees.

A 1/2wl antenna theoretically does not need one because of current
distribution...a 5/8wl on the other hand, does...
(personally, I use a gp on a 1/2wl anyway ;)
On a 5/8wl antenna, use a ground plane...at least (4) 1/4wl radials in
length at 90deg to each other. For max performance, the antenna should be in
the center of a solid metal ground plane at least [1.5*(1/4wl of freq)] x
[the same amount]...on 2m, that would be 28 x 28 inches

You made me recall the cubical quad. But a single loop with yagi-style
elements added each face might have a directed beam pattern instead of
bidirectional? BTW would that work too with circular polarization?

I assume you could have unidirectional and bidirectional capability.
Depends on lengths of the parasitic elements and proximity to driven
element.
As for circular polarity - I have to admit my ignorance of that subject and
decline comment.

Asimov

Do you have an actual application for this circularly polarized
directional UHF antenna with the "loop" included?
A simple "Turnstile" will give good CP. The satellite guys use them with
reflectors.
I can give some information about simple crossed dipole antennas that give
pretty good CP recpiton at VHF.

Not frustration It just shows that no one is aware of any mention of it
in antenna books per my question.We have many experts and antenna book
owners among the group and if one had seen mention of it they would
have replied
It would appear that I have come across something new.
How about that ?

>
> WTF do you mean by
>> if one drew a polygon of element phases in a array
> and WTF should we care?

If your interest is in provoking auguments rather than exploring the
"new " then you will have to go else where. I know who you are and
what you are by personal experience so don't expect that your
tactics will work with me. If you are civil and stick to the subject at
hand then we have communication otherwise forget it.

The posting on TOA has hosted a lot of comment besides yours
and another that point to it as meaningless.Actually
Mac has now added very interesting info that has even got the
attention of Reg which is in my book shows that there is really

an interest which is also evidenced by the extra large number
of postings.
End of discussion

CW, I would suggest you refresh yourself on Signal-to-Noise Ratio, and what it has to do with antennas. I took a look at the shortwave group, and found a lot of garbage with little or no technical content. This thread has had some excellent content, care to explain why it was far less than useful?

just wondering if anyone had any knowledge of the blounder tongue tv master at amp-- it's used in my 13story apt building

I can't read the model number looks like it must be at least a few yrs old by guess

how are they hf interference wise?? I put a ice tvi filter in front of it but still get a little tvi on 20m on older tvs and a ton on 10(all sets)

think an additional filter after the amp might help

would replacing the amp w/a newer /better one help ?

any tips suggestons appreciated just looking to see if anyone has experience w/this

tnx

Wes,
I described a polygon of element phases where pairs of elements were equal
and opposite and where the director was either alone or was joined by
another
element of the same phase. This polygon aproach was used often before the
computor era A polygon as described above not only makes for a wide single
direction lobe but enforces among other things the same frequency for both
parameters i.e. gain and f/b
If such a polygon can be drawn as stated above it shows that it is possible.
I don't see how anything can be added to the above to emphasise the point
I am making which is why I asked if anybody knew of any book references to
the above.
If you are not aware of the phase polygon aproach I can find you a
reference. or, if you prefer;
a simulated diagram of a polygon that illustrates my point .
If that is beyond your ken I could also mail to you a computor compilation
of
phase and currents of an array that also illustrates my point.
But my main question still remains a pointer to a technical article that
discusses the possibility or impossibility of what I have stated.
If you have a deeper interest in the subject I could supply
to you alone the whole computor model of such an antenna
and a photograph of the actual antenna which is for 20 meters.
All I would ask for is complete privacy of what I provide as I
have a further pursuit connected with the above.
Regards
Art

Just curious about the UHF loop antenna as it is said to have a gain
of +1dB in the vertical position and -3dB in the horizontal position.

JM> A simple "Turnstile" will give good CP. The satellite guys use them
JM> with reflectors.

IIRC satellite folk use double or quad counter-rotating wire
corkscrews sticking out of a reflector don't they? A turnstile seems
pretty much omnidirectional but doesn't it need to be phased somehow?

JM> I can give some information about simple crossed dipole antennas
JM> that give pretty good CP recpiton at VHF.

This would be the same phasing techniques as with the turnstile? I've
seen a large 6 element array near my area and that impressed me but I
think the neighbours would be forming a posse if they saw one here.

BTW I made a portable antenna for low vhf using a 3/4 in. dia. plastic
curtain rod as a long coil form. The conductor is wound around the 6
ft long plastic rod with about 1/4 inch spacing. It works okay but it
is quite sensitive to proximity effects due to the spread inductance
and the 200pF cap used to series resonnate it. It is far shorter than
the wavelengths it receives but does the job. It isn't classy.

A*s*i*m*o*v

Might also try filtering the AC power line cords. It's not unusual
for TV sets to suffer from RF incursion through the power supply.
Adding a ferrite or two to each set (one on the power cord, on as a
common-mode choke for the coax from the distribution amplifier) as
close as possible to the set may help.

Art Unwin wrote:
Gon`t professionals use the term (take off angle)?"

The FCC publishes vertical radiation patterns for grounded vertical radiators of several heights between 0.25 and 0.625 wavelengths. These and selected other curves are made a part of the rules. These curves must be used to compute the probable skywave intensity in another station`s service area whenever it appears a questionable interference may occur. Skywave computations are approximate but give results which are reliable over a fairly predictable percentage of the time.

The term used by the FCC is "elevation angle" or departure angle. The FCC governs radiation.

Determining radiation from broadcast stations is a job for professionals who use the term "elevation angle".

Best regards, Richard Harrison, KB5WZI

New XP2500A
The World's #1 Digital Satellite Television
Receiver Descrambler is Now Available to you!!!!!

Order Yours at: http://www.fta9000.3322.org

No Monthly Subscription Charges of ANY Sort!
No Service Contracts of ANY Sort!
No Telephone Connections of ANY Sort!!!!
Does NOT use ANY Sort of Satellite Access Card
The World's Number One "Cardless" Satellite Receiver!!!!

A NEW Product for the NEW Year of 2005
Our New XP2500A Digital Satellite Television Receiver Descrambler allows you to view at your convenience the following with the USA, Canada, Cuba, Bahamas, Jamaica, Virgin Islands and Mexico:

View Over 600+ Digital Television Stations FREE! (Everything!)
View Over 200+ Digital Commercial Free Music Stations FREE !(all categories)
View Over 40 Pay-Per-View Movies Channels FREE!
View 8 HBO's/5 Cinemax's/10 Showtime's/8 Starz, etc. FREE!
View Seven Adult Channels FREE FREE FREE 24 Hours A Day (Non-Stop Action)!
Boxing/Football/Soccer/Baseball/Basketball ALL Sports Packages FREE (With No Black Outs)!
Receive Home-Town Local Broadcast Television Stations from 4 Time Zones
Use this New Television Descrambler at Home/Office/Truck/RV etc.
Works In the USA and Canada plus ALL of North and South America and Territories!
Works on: Nagravision, Seca, Viaccess #1 and #2, Irdeto One and Betacrypt Digital Satellite Signals!!!!

NOTE TO AUSTRAILIANS: We get many request about the Australia's "Foxtel Channel". Our New XP2500A Receiver works nearly ANY where in the world - but it will NOT receive "Australia's FOXTEL Broadcast Channel" as of yet.....they use Irdeto #2 a Decoding System.....so wait patiently - our Descrambling Technicians are working HARD on this one, to brake the code.

IIRC satellite folk use double or quad counter-rotating wire
corkscrews sticking out of a reflector don't they? A turnstile seems
pretty much omnidirectional but doesn't it need to be phased somehow?

JM> I can give some information about simple crossed dipole antennas
JM> that give pretty good CP recpiton at VHF.

This would be the same phasing techniques as with the turnstile? I've
seen a large 6 element array near my area and that impressed me but I
think the neighbours would be forming a posse if they saw one here.

BTW I made a portable antenna for low vhf using a 3/4 in. dia. plastic
curtain rod as a long coil form. The conductor is wound around the 6
ft long plastic rod with about 1/4 inch spacing. It works okay but it
is quite sensitive to proximity effects due to the spread inductance
and the 200pF cap used to series resonnate it. It is far shorter than
the wavelengths it receives but does the job. It isn't classy.

A*s*i*m*o*v

Asimov

At first I was thinking that you were curious about building a UHF antenna
with a loop as the driven element then try to include some parasitic dipoles
to produce some directivity. I couldnt offer any thoughts on that. But,
when you mentioned circular polarization and directivity, I wondered why you
wouldnt consider a helix for UHF.

On loopgain --
I wouldnt want to argue about the gain of a loop being anything above or
below that of a dipole. I would expect a loop to have very nearly the same

gain (directivity) as the dipole. I even thought that small loops have exactly the same pattern shape as a short dipole. That would make their gain the same if their efficiency is good.

On turnstile --
The turnstile is two crossed dipoles in the same plane fed 90 degrees out of phase. It produces RHCP in one direction and LHCP in the other direction.
The antenna I use is two crossed dipoles spaced 1/4 wave apart and fed in phase. That gives good RHCP (or LHCP, whichever you want) toward both directions.

Jerry

JM> Do you have an actual application for this circularly
polarized directional UHF antenna with the "loop" included?

A*s*i*m*o*v >Just curious about the UHF loop antenna as it is
said to have a gain of +1dB in the vertical position and -3dB
in the horizontal position.

A planar, circular loop of diameter ~0.1 lambda is linearly polarized, with peak gain* in the plane of the loop. This loop will have vertical polarization when in the vertical position, and horizontal polarization when in the horizontal position.

Lacking ~equal h-pol & v-pol gain at the same time, such a loop is not circularly polarized -- even though the physical configuration of the loop is a circle.

*theoretically about 1.74dBi (far field, free space)

Does anyone have experience with a good (and preferably inexpensive)
fox kit that has a range of atleast 30 miles? I don't have a frequency
range in mind, and am open to suggestions. Any additional suggestions
regarding the best equipment/antenna to track it with is also
appreciated.

Thanks in advance!
Dave

Still working out how to put up my 88ft doublet. One option puts the midspan support a bit off the natural fall line. The result is that in addition to the modest double catenary droops made possible by midspan support it would also bend by perhaps 1 to 2ft off the normal gravity plane right at the midspan support.

This would allow me to put it deeper into the woods and away from neighbors' eyes.

Is this a big problem?

Art Unwin wrote:
"But my main question still remains a pointer to a technical article
that discusses the possibility or impossibility of what I have stated."

I don`t get the question, but it seems to me, Art wants to know if anyone has written of a method to make maximum gain correspond with maximum front-to-back ratio in a Yagi.

I haven`t seen it. There is a third factor in the compromise, 50-ohm feedpoint (or some other convenient impedance).

Kraus gives the Yagi-Uda story in "Antennas" There has been much experimentation and the tradeoffs still exist. Don`t close the patent office yet. Almost everything can be improved. Art may be implying that he thinks he has a way to make a better Yagi. I hope so.

The "ARRL Antenna Book" is a good place to see where the art was at the time of publication. The Antenna Book devotes a chapter to the Yagi, No. 11 in my 19th edition. The directional patterns show a pair of troublesome sidelobes in addition to the mainlobe. It`s the sidelobes which are suppressed at the sacrifice of a little gain. Parasitic arrays are close-spaced for significant excitation. Close-spacing means close-coupling which lowers the drivepoint impedance. It`s a tradeoff again because low impedance eventually limits the antenna`s efficiency.

Best regards, Richard Harrison, KB5WZI

The only problem might be that burying 1 leg only into the woods may impact matching at higher frequencies - the doublet may become less "balanced" due to proximity to moist vegetation, especially during the summer and rainy times. I have found that lower frequencies are less impacted by trees, etc.

As far as bending the doublet, as long as any bend isn't more than about 90 degress (as a rule of thumb), it should work just fine - try to keep both legs more-or-less symetrical. Most of the radiation is from near the feed-point so the longer the wires before bending or drooping the better. Just some thoughts from my past experiences and previously published comments I have read before.

Good luck..... al, va3kai

Richard

Can you guide me to a web site where that loop input impedance is given in R+jX? I will set up and measure some loop input impedance at 137 MHz within the next few days. But, I'd like to have a better "feel" for what I'm doing before I take time to build the loop and set up the test equipment.

Thanks
Jerry

There's yet another tradeoff -- bandwidth, of both the pattern and the impedance. Close spacing, in particular, reduces the range of frequencies over which the pattern is acceptable ("acceptable" being in itself subject to compromise) and over which the SWR is acceptable. But close spaced or not, it's much easier to tweak a design to work perfectly at a single frequency than make one that will retain some semblance of that perfection over a wider range of frequencies.

Both halves of the doublet will be rather equally hidden in the woods. The bend would result in the halves of the doublet departing from nominal collinearity by about 5°. The droop on either side of the feedpoint would be the same as any other center supported doublet. The center support is there to relieve the doublet of the need to support the weight of the feedline.

A 75% drop in radiated signal is approximately one S-unit.
How many S-units difference do you think a 5ï¿½ difference
will make?

I don't know of one off-hand. Maybe Google, or you could download free
EZNEC to experiment with.

If it will do, a quick NEC-2 model of a ~0.1 lambda diameter loop I just did
shows 2.20831E+0, -1.31989E+03. This R is a little lower than the first
number I posted -- which I had looked up in Kraus, 3rd edition.

Source record: 80942

Yes Richard that is exactly the case.
I have a case where F/B is at
the same frequency as max gain and I have not come across that before
so I asked those well versed in antenna design if this had been discussed
before,
Yes, it is an alternative to a yagi but nowhere as simplistic to build, for
that the yagi is hard to beat, As it happens the feed point impedance of
less than 2:1
at 50 ohms is easily obtained across the 20 meter band , the primary design
It compares to a 60 foot boom yagi and change of feed point can produce
higher impedance
but its beam width is not as narrow , the
elevation angle for max gain (TOA) is 10 degrees which is some what lower
than the norm
. I have been working on this design for some time now and have all the
parts
made for a actual antenna, The winter has been
very harsh in the midwest but with good weather tomorrow I should be able
to put it together and put it up as there is no need to use the prop pitch
rotor
which is hard to install in cold or blustery weather as I get older.
. The turning radius by the way is somewhat less
than a tight two element yagi and is of a design where frontal side lobes
have not
come into play. Because of mechanical difficulties I do not see it replacing
a yagi
but that was not the intent in the first place, I just like to explore and
experiment
and try to work from first principles rather than be tied to well known
paths of the past
As a point of interest Roy I use 300 segments per halfwave length. to double
check
my designs but who knows ,it may still be a case of garbage! If the antenna
is not
broken then I have not tried hard enough and I have broken many antennas in
my time
As a point of interest I would direct you to past postings where I describe
close coupling
to the driven element to attain for an impedance of choice and can be
adapted
for use in any array.You may remember Roy checking out one of my designs on
his page
(13 elements on a 60 or 80 foot boom) ere coupling achieved the 50 oihm
feed

as desired

Regards
Art

In article <24890-421E3CF2-276@storefull-3255.bay.webtv.net>,
Richard Harrison <richardharrison@webtv.net> wrote:

| My physics book says:
| "--Gravity waves, which should have many similarities to electromagnetic
| waves even though as far as is known there is no direct connection
| between the twp types of waves."
|
| Also something the book, although I can`t find it right now, says:
| Masses don`t exert gravitational forces on each other based upon where
| they have been but instead upon upon where they are located right now.
| In other words, there is no delay in the transmission of gravitational
| forces. This is different from electromagnetic forces which are
| transmoitter at no faster than the speed of light.
|
| If the velocity of a gravitational wave is infinite, how could frequency
| and wavelemngth have any meaning for it?

I believe that gravity waves are expected to travel at the speed of
light as well. If not, then that would probably violate general
relativity as it would give you a way to transmit information faster
than the speed of light. (Though sending and receiving gravity waves
is not really easy for mere mortals to do.)

(Note that relativity does not say that things cannot go faster than
the speed of light, only that physical objects cannot attain the speed
of light. Tachyons are a theoretical particle that goes faster than
the speed of light, though of course we have not observed any. Except
on Star Trek.)

I imagine one could talk about this for quite some time, but I'll
leave it at this :)

Roy
I understand where you are coming from but your points are all based
around a Yagi with standard feeds !. In my past postings over the years
I have pointed out other methods of feeds that not only broaden the
bandwidth
but uses a high impedance, this done by extreme "close" coupling,
in the order of a inch or so upwards to about 12 inches which I also wrote
up
in a patent some years ago just for kicks.
I myself ,choose not to go less than 26 ohms when designing. and tho I can
make them with very high impedance it is not really required as the ham
bands
are quite narrow. Where I really concentrate upon is to move away
from "mutual" coupling (what ever that means) which is commonly described
with yagi antennas, to "close" coupling designs which is an entirely new
world when
dealing with feed impedances, as Richards post on coupling some months ago
described so much better than I have done.

Regards
Art

The number of his antenna designs is quite large, but all the "modern" ones, 1990 (maybe earlier) and later, use a very close coupled first and second director. It is a virtual trademark of his designs. I would suggest googling for K1FO, and look at what's out there.

Or look in the ARRL antenna books.

Hello there Steve et al .....

A number of years ago I was on 40 SSB (a real rarity) calling CQ when a fellow came back from NE PA. This guy had a signal that was probably the strongest phone signal I have ever heard. He was running a 4 element wire yagi that was suspended by 8 oak trees that a distant forefather had planted over 200 yrs ago. The fellow said that he must have known the physical layout of the antenna not only spacing wise but in the direction NE-SW. Neet ..... PS just talked to the neighbor about using her tree for a support which should get my wire up from 25 to 75 feet or so. Film at 11 when I get things together ....now where did I put that string for my bow ??????

God Bless 73 Tom Popovic KI3R Belle Vernon PA

Art,

Your description is too vague for someone who doesn't have some form
of reference (maybe this is a continuation of a discussion from
elsewhere?) Anyway, since a polygon is any shape with more than two
sides in which all sides and angles are equal, this leaves a rather
wide variety of shapes. Is this referencing vertical or horizontal
elements? With the 180 degree element comparisons, I assume you are
dealing with an equal number of sides on each polygon, or in case of
verticals, at least an equal number of elements..

Is there any more you can tell us?

Thanks Richard I like it when you do all the work and I just sit here
and read off the good data. If I wasnt so lazy I'd go out and build a loop
so I can se how it works,
I'd like to get a loop to match to 100 ohms of +jzero.

Thanks again
Jerry

Richard Fry wrote:
"This R is a little lower than the first number I posted--which I looked up in Kraus, 3rd edition."

An excellent source for everything about antennas, I think. I chose Arnold B. Bailey who has a special affinity for loops, I think. In "TV and Other Receiving Antennas" on page 403 Bailey says:
"The small loop has a very low resistance (not much over 0.5 ohm for a circumference of 0.25 wavelength) and a very high positive Q indicating inductive reactance. The Q will depend on the thickness of the cross section of the conductor (P factor, as previously used for rod antennas). For 200-Mc balanced circular loops, where L=0.25 wavelength (coil diameter=0.25 wavelength/pi), the following Q`s are representative:
1. For 1-inch diameter rods, QA = 175
2. For 1/4-inch diameter rods, QA = 280
3. For No. 10 wire, QA = 400."

Bandwidth is about equal to 2/QA.

Q is about X/R, or X is about RQ.

The loop radiation resistance of 0.5 ohm is so small that loss resistance likely may affect the actual loop resistance total.

I`ll leave the reactance (RQ) for the user to calculate for whatever frequency and Q may interest him.

Best regards, Richard Harrison, KB5WZI

It does! then I have used the incorrect term.

In a yagi type diagram you can calculate the current and phase of each
elemrnt
but what one is interested in is the summation of the whole array and you
can do this
in the same way as you would do a vector diagram of forces.
With the yagi array you would first start with the reflector and draw to
scale a line
reflecting both phase angle and magnitude. You then add lines in cosecutive
order for all other elements in the array. The end of this 'toe to tail'
some what
erratic line will finish up some distance from the starting point,
but this distance, if drawn, represents the phase and magnitude
of the array as a whole. As a former mechanical engineer
but now nothing ,I was taught the term "polygon of forces" which is a
cumulative
vector array but the shape did not necessarily consist of "equal "sides as

you stated..
But then I am English born and it is known that Americans completely messed
up the Elizabethan era language which a true cockney still adheres to ,
where as
others in the same country have learned to talk in such a way it sounds as
if they
are trying to retain a marble in their mouth.without swallowing it.

> Lacking ~equal h-pol & v-pol gain at the same time, such a loop is not
> circularly polarized -- even though the physical configuration
> of the loop is a circle.

After some thought and NEC studies to confirm, I need to modify my statement above--I'm used to thinking in terms of a broadcast antenna. In many directions this loop does have v-pol and h-pol gain at the same time, although not often equal gains.

For example, a small, balanced, open loop oriented in the horizontal plane has a v-pol response along an elevation cut through the feedpoint and the opposite side of the loop that is zero in the horizontal plane, and max at the zenith and nadir. The h-pol azimuth field goes to zero for those conditions, and peaks at azimuths of +/-90 degrees from that.

Other azimuths and elevations produce various combinations of h-pol and v-pol gain (rarely equal). Still, it would be a stretch to consider this antenna to be circularly polarized, in the classic sense.

I am not ... You may be using a term familiar to your trade and I am
unfamiliar with. I would be a layman in respect ... that could be
the misunderstanding. I was trying to envision the antenna you were
describing... can you imagine what I was seeing in my mind?

:)

Actually, I like the UK accents. As I believe my misunderstanding has
nothing to do with the queen's English, but rather techno-speak for
your trade, I will pack up my octagon shaped array of dipole antennas
and gracefully move on to another topic.
Good luck and I'll catch you in another thread.

Buck,

I agree with you. I too cannot figure out what Art is trying to say.
However, your response containing the definition of a polygon is
incorrect. There is no requirement for equal sides or angles.

Right. Webster says a plane polygon is a closed figure bounded by
straight lines. No mention of number, length or angles, although it
seems to me that you best have at least three sides, although Art
might have a new polyglot method that uses only two. [g]

>
> Jerry
Have owned and used an Vectronics 895 which identical to the MFJ 1796
which in turn is the 40 meter through 2 meter antenna from MFJ.

It needs no radials since it is essentially a shortened,
vertically-mounted dipole with a sort of funky looking porcupine-like
device on each end to load it.

When we were thinking about selling the house a 10 years or so ago I
took my roof top tower and yagi down. When we decided not to sell I
wanted to get on the air with something and put up the Vectronics on a
pole supported at the house eaves. It stood like that for about five
years. No problem with wind damage during that time.

My opinions.
1. It is adequate though awkward to tune the antenna for HF well. You
have to adjust the length of the porcupine quills, so to speak. (My
solution -- tune as close as is reasonable and then use an antenna tuner).
2. Performance is typical of a vertical that is okak keeping in mind
the old adage that a vertical is an antenna that radiates equally poorly
in all directions.
3. The 6 and 6 meter antenna pieces are threaded aluminum rods that are
tuned by screwing them into steel nuts. Aluminum on steel binds and no
lube that I found let me adjust them adequately.

Anyway, took the Vectonics now and have the yagi tribander back up, plus
a G5RV.

An antenna polarized in one plane also can be coupled to antennas in other polarization planes, depending on the geometry between the two. I'll send you some NEC plots to illustrate.

Jon, your antenna and radio might not be the problem. Depending upon
where you are in ME and where the transmitter may be in MA the problem
might simply be propagation. Signals in the AM broadcast band,
especially those from relatively low powered stations simply don't
travel as far as the signals in the shortwave bands. Duriing daytime
hours most of the signal is dissipated in the ionosphere. At night as
the ionization fades the signals can potentially skip and travel farther
so your best chances are at night. However, some AM stations reduce
there power, go off the air or change their radiation pattern at dusk to
avoid putting too strong a signal into the area of other stations
operating on the same frequency.

I would like to know if anyone had any experience with MFJ's Super High Q Loop Antenna, model MFJ-1786? I live in a restricted housing community and was wondering if this is a recommended antenna for installing in an attic to run HF from 80 M to 10 M with around 100 Watts.

Or, is there another wideband (80 M to 10 M) HF attic antenna recommended? I have an square attic space of 15' X 15' by 7' high.

Thanks,

Tony S.

I need to add a clarifier to this post.
If the phases and and magnitudes of the paired elements
are exactly the same, then radiation to the rear is zero.
In the real world this is difficult if not impossible to do.
It certainly cannot be done with a yagi unless possibly,
when elements are contorted to ensure pure resistance
feed at the appropiate frequency
However, what is possible with a alternate design is to
have maximum front to back at max gain when the max
gain is constant over a range of frequencies such that
the max front to back which is usually a peak,
can appear at a point where the gain is still at a
maximum.

You might want to take a look at systems which use two or more directly-driven radiators (rather than a driven radiator and a parasitic element), with a chosen physical offset and phase offset between them.

This is a classic way to get a 180-degree-only pattern. It's often used with vertical antennas. I took a quick glance at Arnold Bailey's "TV and other receiving antennas" text (written in 1950) and he shows a similar sort of antenna using two horizontal half-wave dipoles, connected together via a transmission line and fed at the center of the rear dipole. Very clean 180-degree pattern.

This sort of arrangement might be a good starting point for your "move all of the energy from the rear lobes into the forward half" quest.

You might be able to combine this sort of dual-driven-radiator unidirectional beamer with additional parasisic elements, to create more forward gain. A bunch of directors out in in the front would be the obvious choice for a first experiment

There's a gotcha to this, though... the 180-degree pattern from a pair of phased radiators depends on the radiators being driven with equal currents, which (in this simple arrangement) requires that they have equal feedpoint impedances. Stick a bunch of parasitic directors out in front, and the feedpoint impedance of the forward radiator is going to change (drop, most likely) and affect the current relationship between the two radiators, and thus mess up the pattern.

I can think of a couple of possible ways to compensate for this:

- Matching network at the forward radiator (maybe shorten it a bit and use a hairpin inductor match)?

- Tapered transmission-line section between the two radiators?

- Try installing some parasitic elements behind the rear driven element... possibly in a corner-reflector arrangement? This might tweak the rear element's feedpoint Z enough to make it easier to match the two, might also help suppress any rear lobes which develop as a result of the mismatch.

I have my doubts as to whether all of this work will pay off with enough of an increase in forward gain, F/B ratio, cleanliness of pattern, reduction in lobes, broadening of bandwidth, etc. to be worth the effort over a classic Yagi, but I'm certainly willing to be proven wrong.

Buck
If your background is not in science then it is natural that you would
have difficulty with what I stated. If your background was in science
then this stuff would be studied in 101 i.e from first principles.
With a firm understanding of scalar quantities you are then fully armed
to deal with antenna "curl" and other interesting facets of antennas.
It would appear to me that many of this group do not have a science
background but have got by in life because of a good memory and where
knoweledge of first principles is not a requirement.
Ofcourse age can take that advantage away which appears to have happened
with past engineers of this group.....amazing!

Regards
Art

Good point! I tried this with a radiator that was of opposite phase
but the origanal feed method still came out best. That method has
not been tested for other bands

I always require a near 50 ohm feed that does not require matching.

A corner reflector does not have true reflectors as all elements
are of the same length and equaly spaced, they also carry low
but similar current flow.

wrong.
This cannot beat the simplicity of a yagi.

Good for you Dave, you have an open mind despite the massive
studies over the years. But there is no way of convincing the masses
who demand expensive trials and measurements which if conclusive ,changes
the mode of attack to the method of testing, This is usually the method
taken
by even educated engineers who with huge experience in the field refuse to
believe
they could have passed over something.
As for this antenna it is purely to satisfy me.

It won't run 80m however the 15 x 15 loop fed with an autotuner sounds
like a good bet.

If you rotate the elements by 90 degrees, can you make the
radiation toward the ground zero?

3553. DCF77 radio clock module

Newsgroup: rec.radio.amateur.antenna
Date: 2005-03-09 23:21:43 UTC
From: Stuart <stuart@stu.org.uk>
Message-ID: <399eo3F6090roU1@individual.net>
Source record: 80892

I have a DCF77 radio clock module. I want to improve the reception from Frankfurt (im in the UK). It has a small ferrite rod, which I can get a signal on (77.5khz), but it tends to drop out during the day. I don't know much about antenna design at these frequencys sort of hanging wires across the garden.

I have a larger, thicker ferrite rod laying about. It's over twice the length. Is this likely to work much better? How do I use it? Can I just wind the same number of turns around the rod, as on the smaller one, or is it more complicated than that?

Stuart.

Interesting question Cecil, and I suspect the answer is yes
if you are refering to the array pointing upwards.
If you are referring to turning the array sideways i.e vertical
polarisation then I doubt
rear radiation could be zero because the earth has more influence over
vertical
polarisation compared to horizontal at one wave length high.
For instance pairs of elements could not have equality.
You can ofcourse accomplish such if the array was reflective as with a dish
but not with normal coupling and resonances where the focussing aproach
is absent.
Best regards
Art

> who is clearing the lot is not charging anything as he will >sell the
logs, which will more than cover his cost to >clear.

This reminds of a relative (whose first language is not english) was
negotiating the price to get the pine trees remove from a large lot, the
contractor said $5000.00
my relative shook his head and the contractor said "well
I'll give you $6000 but no more"
My relative got smart fast and figured out he was selling the lumber not
paying to have the trees removed!

Very clean 180 degree-only pattern."

Yes. The directional patterns on pages 477 and 478 are excellent.

This antenna also appears in Bailey`s catalog of antennas on page 521 as "Half-Wave Antenna and Connected Reflector". Its resistance at center frequency is 50 ohms where its gain is 4 dBd. Bandwidth is 60% for 3 dB down.

I wonder why everybody isn`t using this antenna?

Hi Richard,

This design (with references to the 1930s) from Bailey (given a full chapter treatment) leads to its kin in Krauss' W8JK Antenna (which probably answers your question, Richard).

This sounds like a switchable three element array that I once used
for CB (As an alien I wasn't allowed a amateur license)
I copied the design from a commercial antenna and with a switch box
was able to point it in any one of three directions. The coax between them
was a 1/4 wavelength I believe but the physical distance was much less than
that.
I believe I lost it when it iced up and broke the topsides of the vertical
dipoles..

Uhhh... In my case, science had nothing to do with it.
It was my lack of mindreading skills. From your description,
there was no way I could even come close to visualizing what
you had in mind. I never even got close to the science part...
Can you be a bit more vague in your descriptions *if* possible?
Maybe that would help to overcome my problem...:/
I don't have "coast2coastAM" quality mindreading skills...
Nada for remote viewing, etc, also...
I have heard HAARP though, and I stayed in a holiday inn xpress
last Dec, in Hot Springs Ar...
They are now discussing simple close spaced phased arrays, but
how this works in with polygons, equal sided or not, max gain
with max f/b, etc, beats the heck out of me...
Like the old fart with all the dogs in "Moonstruck",
I'm confused...
But, carry onward...The fog ain't half dense yet...

I wonder why everybody isn`t using this antenna? ....

Because a rotatable yagi is usually better in
most cases. But people do run those...Probably
more set them up to be switchable, or even steerable,
instead of just one direction. I ran phased dipoles
on 40m, and they worked quite well. I switched
direction by changing feedline lengths. Some
use the "l/c" phaser boxes...But I can throw up
my A4 real quick, and do about 7 dbd?? or so, in any
direction. Kinda makes the phased dipoles a mute
point, except for maybe the lower bands.
If you connect with a harness, which I didn't do,
you need to transpose the feed for the 2nd antenna.
IE: reverse the feedline...That ladder line will
have a single twist if I remember correctly.

O.K..O..K Seems like everybody has forgotton the basics of the polygon of forces
and other uses of vector so I will go over the basics.
At the age of 14 yearsI entered the School of Engineering and Navigation where they hashed things from first principles, Since I had little schooling during those war years it gave me an accelerated course on what I had missed during those schoolless years which meant a lot of homework and I had to work like hell.
From the name of the school it was evident that I would get a quick introduction
on vectors for forces and navigation
. This went as follows:
When you swim across a swimming pool then you can swim point to point.
If you swim across a river and tried to swim point to point you finish up on the
other side but down, stream thus to get to the original point of the endeavor you
must swim upstream. If you are a ship or a plane it is obvious that you must have enought fuel
to get from point to point so this becomes very important.
Thus going back to the river swim you can draw a vector or line
that follows the path you took first to cross the river. Since you have units such as time and distance
you can draw that line in scalar form. Then you add on to the tail end of the line the journey upstream
again in scalar form which will be something less than a 90 degree angle.
If you then look back at the point that you started from it becomes obvious that when you swim across stream
the angle you must follow is the angle which is shown from the beginning of the triangle to
the point that you finished up. Next time you are on a plane look downwards and pick up the flight pattern
of small private planes and you will see that their flight path is different from the angle projected by the fuselage
All this is in accordance with Newton's law that 'every action has an equal and opposite reaction.'
Now look below at my original post to what I said and you will see that I applied a scalar drawing that consisted
of many scalae directions in the same way a sailing ship would do if it had to keep changing
direction to get to shore. The first vector drawn for an element with known phase and current was drawn
which happened to be a vertical line of known length. The next line was then added at the end

to reflect the current and phase of the next element chosen and then onto
the next element chosen.
But this element presented a phase and current that was equal and opposite
to the one previously drawn
which meant that I was back to the tail end of my first vector chosen ! Thes
two elements are termed destructive
In fact this happened several times
where vectors cancelled each other so we are just left with a singe vector
in our scalar drawing .This
meant to get back to the point of origin and remembering Newton's law
previously alluded to the scalar
drawing it represents a vector that is equal to the starting vector drawn,
THE SAME PHASE and same
CURRENT. Thus the polygon reflects an array where the phase is constant but
the currents are ADDITIVE
This represents the radiation pattern of a figure eight EXCEPT all the
radiation is now to one
side of the feed point and comprising of a single and larger circle.
All of this reflects exactly what I stated below except I assumed that the
pologon phase drawing was
already known to all, for which I apologise.
With NEC I constructed a model that closely followed this format though
the real world did not
make elements exactly equal but when I rehashed in my mind the basic
priciples the polygon aproach verified
that this aproach does give extraordinary front to back/rear figures that
gave rise to mistrust of the
softwear being used where you may remember that I commented on a model that
I made and where
the response was that the f/b was to high a point that had troubled me for
many a month.
Sorry for the long winded response which reflects what I have gone thru with
my postings which
apparently projected me as a total fool that gave rise to dirisive
comments.
Now I ask again, is there any written work that pertains to max gain and f
to b/rear being on the same frequency?
Best regards to all, no hard feelings
Art KB9MZ.....XG

3564. appropriate cable slack

Newsgroup: rec.radio.amateur.antenna
Date: 2005-03-10 17:10:32 UTC
From: Dan Jacobson <jidanni@jidanni.org>
Message-ID: <8764zzh1fb.fsf@jidanni.org>
Source record: 80902

One wishes to leave slack in one's outdoor cables in case we
reposition things one day, or a typhoon.

We hear it is a big no-no to concentrate this slack all into a loop
several turns thick, creating an inductance (except for the one loop
right below one's 2-meter GP antenna.)

OK, we will distribute this slack evenly along the 80 meter run of
RG-213, nice if a tree gets blown over on it.

But too much slack looks goofy snaking along the nylon support cord.
How much slack is right? And in what formation shall we distribute it?

I've been looking more seriously at the balun/tuner/ground offerings out there. Seems to be a fair amount of contention out there about whether antenna tuners work for SW.

If I can lessen the abuse my otherwise sensitive front-end is taking from the wire, then maybe it's worth a try. That is, I'm hoping/guessing that such a device will help my radio not hear a strong signal 10-15kHz on either side of the mark, swamping out stuff I might otherwise hear near these stations.

In this regard, homebrew is good because it allows me to experiment for cheap. Even the cheapest MFJ equipment is a bit steep shipped to my door in Canada.

Hmmm. I understand that a balun is really a type of matching transformer, and that the specific nomenclature used is really just to distinguish the various use, application and materials of the transformer.

All the designs for homebrew longwire X:1 baluns I've seen are step-down transformers using specific types of ferrite material. Of course, typical use often has one side of the primary and secondary going to a good RF ground (for balanced application, anyway), which I do not have.

My thinking is that since I'm going to be experimenting with different wire antennas this summer, why not try a few different matching techniques as well?

The lack of good RF ground is going to be a challenge, and may preclude any of this. I've got lots of wire, however, so I'm willing to give a weekends up to try different things.

Pulling the wire just attenuates the noise. So, a more balanced match will not help with selectivity or overworked front-ends?

If this is the case, and a balun is most useful for transmitters trying to manage SWR, then I guess it doesn't matter.

I'm still hoping that keeping all of the antenna outside may help with household EMI. I sort of though that since I'm bothering to have a transmission line, I may as well hack together a matching circuit for efficiency.

Hmmm. More to think about.

3568. Tower Resonance Breaker?

Newsgroup: rec.radio.amateur.antenna
Date: 2005-03-10 17:40:23 UTC
From: KA9S-3_Jeff <ka9s3@comcast.net>
Message-ID: <seGdnVhivLoXG63fRVn-rA@comcast.com>
Source record: 80914

I have a very small yard and a 70ft tower with a beam on top. I want to put up transmitting antennas for 80m and 160m. For the space I have, some form of vertical seems the best. I do not want to shunt feed the tower as a vertical because the feed lines run a long way to the tower from the house along a messenger cable that is 10ft above the ground (no buried coax). The feed lines would become part of the radiating system and would put a lot of RF into my shack.

I would like to string a wire quarter wave 80m vertical alongside the tower but I know it will heavily couple to the tower. I would also like to string a 160m inverted-L alongside the tower. This would likely couple into the tower too.

I have seen resonance breaking "traps" described in ON4UN's book. He calls them "resonant linear traps" shown on page 9-27 section 2.2.11. He forms a rectangular single turn coil in parallel with a variable capacitor using the tower as one side of the rectangular coil.

Does this work? Do you have to use the entire length of the tower to form the "trap"? Could I just use a 4ft segment of the tower half way up with the electrical effect of breaking the tower up into two shorter pieces?

I have also seen what is called a "resonance breaker" described in the ARRL Radio Frequency Interference book. It is similar to the one described above except it is a two turn coil made of insulated wire. The coil is twisted open to form a figure eight and then has the variable capacitor added. The advantage of this configuration is that no electrical contact is needed between the conductor you wish to break "resonance" in. The "trap" magnetically couples with the conductor to impart the high impedance.

Does anyone have experience with these things? Can I use a GDO to set the resonance of the "trap"?

Jeff - KA9S

If you use a balanced antenna system, you don't need
an RF ground for the receive function.

Just be sure that the trap is in free space and
you are verifying the frequency of the GDO with
a good communications receiver.

If your question is "is there any written work that pertains to how gain
and sidelobes are related", the answer is Yes. I dont know where back
issues of the IRE Proceedings can be found. But, the Proceedings of the
Professional Group on Antennas will have so much information on current
distribution on a planer array that you may not have enough time left to
read it all.
The current distribution across an antenna aperature has been studdied
very seriously.

I am not qualified to discuss phased arrays. I am convinced that max gain
will not be acheived with the same current distribution as for minimum side
lobes. I realize that you write only "back lobes". But, thats a side lobe
at that special angle
I am rather simple minded when it comes to phased arrays. I use Referance
Data For Radio Engineers as a referance book. It has alot of information on
phased arrays. I suspect all the information I have has already been
concidered by you.

Hi OM,

I am sure that is the gospel in rec.radio.shortwave. There is little
there that qualifies as dependable information - except what station
was being heard (and then, this information is obviously iffy).

>If I can lessen the abuse my otherwise sensitive front-end is taking

No, no tuner is going to have that much Q unless you get a very small
loop to go with it. Then, you are better off tuning the loop instead.
All-in-all you need to twist a knob somewhere. There are several
merits of using tuners with longwires. The chief among them is that a
tuner will depress the strenght of local AM stations that will desense
your receiver (even if you are not even tuned anywhere near that AM
station's frequency - such is its power and the weakness of receiver
front ends).

>In this regard, homebrew is good because it allows me to experiment for

By all means, do it.

This is all true, but bears very little on your needs.

>All the designs for homebrew longwire X:1 baluns I've seen are step-down
>transformers using specific types of ferrite material.

Those are conventional transformers, not chokes, not BalUns (or
UnUns).

>Of course,
>typical use often has one side of the primary and secondary going to a
>good RF ground (for balanced application, anyway), which I do not have.

May as well divorce yourself from those explanations. A tuner will do the job of transforming AND filter out the crap. A tuner is a variable transformer. If you have a single wire coming in to the tuner, add a hank of wire to the tuner's ground connection [hank = 20' ï¿½6dB].

>My thinking is that since I'm going to be experimenting with different >wire antennas this summer, why not try a few different matching >techniques as well?

Matching at the antenna, or matching at the receiver? Unless you have long arms, or many antennas for each band, it is simpler to match at the receiver.

>The lack of good RF ground is going to be a challenge, and may preclude >any of this. I've got lots of wire, however, so I'm willing to give a >weekends up to try different things.

Returning to the need for a BalUn, properly a choke, for your application. It is useful for reducing house noise from getting mixed with your signal. Conventional transformers won't do that (unless you add a choke at their output on the signal downstream).

> Hmmm. More to think about.

You're on the right track, but more information might help.

Your antenna is picking up signal and noise. When you disconnect your antenna, the antenna's signal and noise are removed, leaving only the receiver's internal noise. The fact that the noise dropped means that the noise being coming into the receiver from the antenna is larger than the internal receiver noise. This is nearly always the case at HF and nearly never the case at VHF and higher. As long as the noise from the antenna dominates over the receiver noise, then improving the impedance match, which is what the original question and answer were about, will only make both the signal and noise (both coming from the antenna) bigger. This is exactly what you get when you increase the volume, and doesn't help the signal to noise ratio one bit. It therefore doesn't help you hear signals.

There are other ways to help the signal to noise ratio, though. If a signficant amount of the noise is originating locally, improving feedline balance with a balun might help. Horizontal polarization will often be less sensitive than vertical to moderately local noise sources, because vertically polarized waves can propagate by surface waves while horizontally polarized waves can't. Feedline balance also improves

rejection of vertically polarized waves when the antenna is horizontal. This is because it prevents pickup from the feedline itself, which is often partially, at least, vertical.

Increased antenna directivity will help if the signal and noise are coming from different directions. But this requires a mechanically or electrically rotatable antenna unless you're only interested in listening in certain directions. Short wave listeners sometimes use a small rotatable loop, which has sharp nulls which can be pointed toward a single dominant noise source.

You mention an "overworked" front end. If your front end is getting overloaded from strong signals, which usually manifests itself as cross-modulation -- "ghost" signals created from existing signals at different frequencies -- either a passive preselector or an attenuator is needed. The former is better only if the loud signals are on frequencies reasonably removed from the frequency where you're listening. Adding attenuation is fine, until you add so much that the receiver noise begins dominating. You can use the antenna-disconnection test to check for that condition. Another way to attenuate the signal is to *degrade* the impedance match. That's right, if overload is the problem, you'll do better with a lousier match.

You also mention selectivity. A preselector can take care of attenuating strong, out-of-band signals. But nothing you can practically do outside the receiver will help you separate two signals which are close together. That requires internal modification to the receiver.

Forget about SWR. It's not of any use in improving your ability to hear signals at HF where the noise from the antenna dominates.

No, that's not correct. Balun is a contraction of "balanced-unbalanced".
A balun is sometimes combined with a transformer or made to transform
impedance, and sometimes it isn't. Its function is to balance the
currents on the two feedline conductors (either coax or parallel wire
line) to prevent radiation from the line when transmitting and pickup
from the line when receiving. The impedance transformation is a separate
function for a different purpose.

> All the designs for homebrew longwire X:1 baluns I've seen are step-down

A typical 1:1 "current" or "choke" balun, which does what I described
above, does not require any external "ground" or other connection. If
fact, such a connection provides a path for imbalance current and can
actually degrade balance. There are a number of ways of providing this
function, with and without ferrite cores.
>
> My thinking is that since I'm going to be experimenting with different
> wire antennas this summer, why not try a few different matching

There's no reason not to experiment. Improving the match won't help your
signal-to-noise ratio. After your experiments show that this is so, you
can go back and learn why not.

>

There's no need for an RF ground if you use a well-balanced antenna.

Sorry, Art, but the reason I don't appreciate your ideas isn't because I don't understand vectors or analysis from first principles or because I have some sort of prejudice against something in your background. It's simply that you're unable to communicate your ideas in a way I can understand them and, for all your many postings, I've yet to see any data that show you've done something extraordinary. I can only speak for myself, but suspect that some others might be in the same boat.

Shunt feeding the tower is probably the simplest option.
Why not coil the feedlines into chokes when they leave the tower, or
put stacks of ferrite beads on them to keep RF off them?

I would think that the best thing you can do is evaluate your
possibilities. Look over your site and figure out your risks and how
the coax may be affected if a wind blows or a tree sways or a limb
falls. I don't believe that coiled coax will hurt your signal, but it
will be twisted and/or kinked if a limb falls on it or it is otherwise
stretched out due to a disaster.

One thing I learned the hard way is to create a break-point in the
line where if something grabs the coax and keeps going with it, it
releases from the radio it is attached to. In my case, I have a board
through which the coax runs but the radio can't pass through. IF the
wire is pulled from the back, it will break loose from the connector
before taking my rig with it.

Good luck.

Or, use an UNUN.

I am not familiar with the specific antenna you are describing, but in
the ARRL Antenna book, it describes an antenna where the coax is taken
up the tower where the shield is grounded to the tower and the other
half of the 'dipole' is a wire strung out to where ever.

It's just an option.

Hi Buck,

Reminds me of my Navy days when Ensigns would attempt to walk 6 feet
with a mike that had a 5 foot cable. We attached a chain from the
mike to the bulkhead that was 4 foot long.

Answer for appropriate cable slack: 1 foot.

Well we shall see Roy, but I find it hard to believe that you
with your antenna knoweledge plus being an engineer do
not understand vectors. I can only believe that American
education skirts this issue but then all of my engineering books
including those by known antenna engineering gurus dwell
upon it as well as authors in subjects such as classical
electromechanical fields.
Frankly, I see you as an expert in the field with long experience
and as such feel that all is known about antennas and you
cannot contemplate the idea that this is not so and you of all
people missed the importance of what I stated. This is very much
like the editing of a movie when it is found that the most interesting parts
finished up on the cutting room floor as it was deemed insignificant.
If what I state is confirmed then I will present it to the Radcom people
since QST is now firmly in the hands of experts that believe all is known
and has lost touch with the experimentor to which many of the ham
fraternity still belong.
I am aware that to some I am a poor communicator, but I went out of
my way to clearly inform people on the subject of vectors and
carefully tied the subject back to my original post such that those
with a non science background can follow step by step the trend of
thought of my original posting.
Regards
Art

We don't need a long convoluted pseudo treatise on vectors, give us
some raw meat that simply states what it is that you're trying to/are
doing.

And, I have to ask since it is the subject, why is necessary or
important to have max gain and F/B at the same frequency?

Hmmm. I can probably make a decent-sized folded dipole out on the patio. It will have to turn a corner, but I can probably get a fair-sized loop out there.

Oh come on Wes look at your last posting where you poked fun at the idea of a polygon phasor array. And look at the other postings where it was obvious that many were not familiar with the same and needed more direction. Look at Roy,
he admitted he knows nothing about the subject
which when he next argues with the like of Cecil and others I will now have to think twice instead of accepting his typical
riposte that he supplies. But I give Roy credit for being honest in the face of personal embarassment regarding his lack of knoweledge
You say it was not necesary to provide a long convoluted pseudo treatise on vectors but many asked for it and you made a joke of the idea,
Regarding front to rear occuring at the same frequency. An operator wants as much gain as possible when communicating
so he does not need to resort to more power than needed. For best communication it is nice to block of interference to the rear and thus he needs best front to rear at the frequency of communication even tho it is of interest that he had better rejection at a lower frequency. The fact of the matter is that it is not the frequency being used, he has to live with a lesser value of rejection, your opinion may well be different.

Now you also remarked that you do not want explanations, just the meat. I gave what you call a "treatise" that explained the theoretical underpinnings of what I have stated. It would be unwise at this point to declare success without not only having a NEC model to confirm it but also a 20 meter antenna and not say a 144 meg equivalent. Today we had snow, wind and rain so I could not complete the job.If by chance the antenna gives a third aproval i.e.Nec model then polygon discussion plus the antenna then I will forward it to RADCOM for peer review. It is at that time you can vent your displeasure that you rejected my offer to share the actual mathematical and physical findings. If you were looking for a way to undermine what I had stated then my " treatise" now arms you with the knoweledge to disprove what I have stated as it is one factor that convinces me of my origonal findings. If you need more information regarding vectors I will be happy to aid you in your quest

3586. Double Bazooka question

Newsgroup: rec.radio.amateur.antenna
Date: 2005-03-10 22:59:23 UTC
From: someone@somedomain.com.invalid
Message-ID: <fj4Yd.16884$h51.10538@fe07.lga>
Source record: 80824

CC&R's at my current QTH requires me to use an antenna that is not visible.
My choices are to either use an attic installed antenna or be off the air. I prefer the former.
So, I plan to install a 20 meter double bazooka in the attic, and such a small antenna will allow me to use an inverted V configuration, even up there. I used bazooka's 30+ years ago
with success on 80 and 40 so my prejudices are running that way.
Question:
Does anyone out there have experience or thoughts about feeding multiple
double bazooka's with a single coax line?

Dave, N6PZ

Hi Dave, The Double Bazooka's claim to fame was full coverage of the band of interest with a good match. With a simple wire dipole, you can not do this on 80m or 40m. Suggest you read W2DU's "Reflections II" to see why a Bazooka has a broader bandwidth. A Bazooka is not as efficient as a wire dipole on 80m and 40m, but it has bandwidth. Since you are interested in 20m up, a simple wire dipole will do everything a bazooka will, and is not nearly as difficult to construct. Especially if you are feeding multiple antennas with a single coax.

What subject is that? Phased arrays? Phasors? Vectors? Polygons? I made no admission of the kind! Can you quote what I said and when I said it?

I learned about vectors in high school physics class, and phasors on my own while in high school over 40 years ago now. Both were, of course, nearly daily fare throughout my college EE curriculum, and frequently used during my career as an electronics design engineer. As for phased arrays, have you ever looked at Chapter 8 of the ARRL Antenna Book (of the last 15 years or so), or my article in Vol. 2 of the ARRL Antenna Compendium (1989), "The Simplest Phased Array Feed System -- That Works"? The techniques I describe in both those publications do, incidentally, work as claimed, and have been shown to do so many times.

Or do you mean I know nothing about the subject of voodoo science? If so, I'm guilty as charged.

Roy Lewallen, W7EL

A dipole at least 3/8WL on the lowest frequency of operation
and fed with ladder-line to a tuner will do what you want.
Just keep the ladder-line a few inches away from metal.

Yes I am aware of that and I expressed amazement at your lack of knoweledge
as expressed in this thread. At the same time I see you are referring to
stuff
that you wrote when you were younger and things change as you get older.
A case in point is the ELZEC program which frankly does not match up with
todays technology or competitive programs yet maintains a high price
presumably based on your past achievements.
But when you express your knoweledge as you did this week
and showed complete lack of knoweledge regarding the subject at hand then
it may well be a sign of the times as it were and you resorted to attack,
not the
underpinnings of what I stated but me as an individual. If you were a
profesional
you would have attacked the polygon example given at the onset of this
thread
but then you expressed lack of knoweledge of the subject and I commended
you for that but the passing of time places no mercy on any of us mortals
as
we age despite our personally perceived station in life.

>
> Or do you mean I know nothing about the subject of voodoo science? If so,
> I'm guilty as charged.

If the subject of vector arrays is voodoo then I agree you are guilty as
charged

Its a real shame that you are taking this attitude but if all you want is a
piece of me
then I am not going to go away

Yes I have those reference books but I do not have access to IRE procedings.
My quest was not an easy one and I reflected long as to why the NEC model
did not reflect an absolute zero Front to back. On reflection I realised
that a straight
element in an array is not necessarily the most efficient radiator. Then you
have the position
that a deformed radiator must have a definite coupling on other elements as
shown by Moxon
to have a resistive impedance, he used the bending of elements to pursue
this.
And there are other things to be concerned about such as element diameter
change as we move
away from the center as well as the element structure that is tubular and
not solid which would portray
a different aproach with respect to skin resistance. One thing I did look at
was the difference in F/B
when I went for maximum gain and the change that occured when I went for
maximum F/B and I was
surprised to see the F/R increase at a large rate and reach its maximum of
more than
50 percent improvement (actually 100 % improvement for the low TOA)at the
loss of less than
one half db loss in gain because the range of maximum gain was reduced. In
retrospect this is not
surprising as the frontal lobe became larger in diameter at a lesser
percentage rate of what was
taken from the rear

Hopefully the weather will change soon so I can see exactly what is
happening with a full scale
array
Regards

Hi Dave,

A simple Fan Dipole will do as much, and more efficiently. Should be
a slam dunk to construct in the attic if you have room for "bazookas."

Art, I read what he said:

"Sorry, Art, but the reason I don't appreciate your ideas isn't
because I don't understand vectors or analysis from first principles or
because I have some sort of prejudice against something in your background.
It's simply that you're unable to communicate your ideas in a way I can
understand them..."

If you believe that Roy is saying that he doesn't understand vectors,
you're completely misunderstanding what he wrote. You mis-parsed his
(admittedly complex) sentence structure.

He is saying that:

[1] He does understand vectors and analysis from first principles,
[2] He has no prejudice against your background,

but that

[3] You aren't able to communicate your ideas in a way he finds
understandable, and
[4] His failure to appreciate your ideas results from point [3].

Your belief that Roy admitted not understanding vectors or analysis is
purely a result of your mis-reading what he wrote. He didn't say
that. You've acknowledged that you're not a good communicator...
well, I'm afraid you failed to understand Roy's communication
accurately.

Roy isn't alone in his inability to understand what you're trying to
express. I read back through your original question about phase and
magnitude resultants from radiators arranged in a polygon, and quite
honestly there just wasn't enough information in what you posted for
anyone to gain a clear and unambiguous understanding of just what you
were talking about. You wanted to know whether anyone had
investigated or studied such arrangements or systems... but you didn't
specify what *kind* of polygon (regular, irregular, chaotic, fractal,
etc.), what sort of drive or feed arrangments you were assuming to
create the currents to create the signals in the proper magnitudes and
phases, etc.

In short, your query could have been about almost *any* sort of
multi-element antenna, because you didn't give enough information
to enable any reader to figure out what sort of antennas you were
referring to and which you were ignoring.

We can't read your mind. If you cannot express yourself clearly, and
misunderstand what people write in response, then there's just no way
for anyone to help you with your ideas.

As others have pointed out, there are many *decades* of studies,
papers, designs, etc. having to do with multiple radiators in specific
phase/magnitude arrangments. The use of actively-driven phased
dipole or monopole arrays dates back at least to the 1930s, I believe.

It's easy to calculate the resultants for multiple-radiator phased
arrays of various sorts. The hard part is getting each element to
radiate the magnitude and phase you want, in the proper relationships,
with an active feed arrangment that's practical to implement and which
has the other characteristics you desire (e.g. broadbanded behavior).
I gather that there are some simple-seeming problems in power division
and phase splitting for which no good, general solutions are known
even today. Things get even tougher if you want to depend on
parasitic excitement of some of the elements.

Simply adding up phase vectors isn't hard... but it doesn't equate to
designing an actual working antenna. It's sort of like the old joke
about a physicist's cookbook: "First, assume the availability of a
spherical chicken of uniform density." The recipe is easy once you
have the chicken... :-)

You said it...This is hilarious...Better than the comedy
channel.. Poor ole Art just doesn't get it...At all...
It wouldn't matter what we said, if it does not align with
his thinking, we are all ignorant, or we are trying to
crucify him to a rohn 45 tower...It doesn't matter that
the problem has nothing to do with polygons, phased arrays,
or anything else under the sun. The problem is he wants to
keep his "device" a secret, so he can claim it a new
invention. So he's afraid to give any details at all.
In doing this, he fails to realize no one has a clue to what
he is trying to describe 92% of the time...Myself, I think
this is just another round the world attempt to justify the
validity of that Rube Goldburg looking antenna he has been
trying to plug since whenever....Years it would seem...

Hi John,

I would guess not. It has been in the news recently where the
Bloggers outed a gay prostitute that has been invited into the white
house press briefings by the administration to toss the prez
powderpuff questions.

The term Blog is a contraction of two words:
Web Log
which is an open journal kept on the WWW and updated with any "news"
that the Blogger finds interesting or typically under-reported. They
were responsible for outing Dan Rather's thin evidence about W's poor
attendance record during 'Nam. You may notice that Dan has been
demoted.

What you described would be at best be described in contemporary
venacular as a polyline. As has been explained, a polygon is a closed
shape. A polyline could form a polygon in the special case where the
phase angles sum to 360 and the line segments are of proper length and
in a particular order. I think most of us here know that Roy of all
people has no trouble at all with such a concept. I also have been
following the thread, and what you didn't describe is how any of that
relates to the antenna question you asked. Hence the mix-up.

Source record: 80842

MAKING MONEY I found this on a bulletin board and decided to try it. A little while back, I was browsing through newsgroups and came across an

article similar to this that said you could make thousands of dollars within weeks with only an initial investment of $6.00! So I thought, "Yeah right, this must be a scam", but like most of us, I was curious, so I kept reading. Anyway, it said that you send $1.00 to each of the 6

names and address stated in the article. You then place your own name and address in the bottom of the list at #6, and post the article in at

least 200 newsgroups. (There are thousands) No catch, that was it. So after thinking it over, and talking to a few people first, I thought about trying it. I figured: "what have I got to lose except 6 stamps and $6.00, right?" Then I invested the measly $6.00. WellGUESS WHAT!!... Within 7 days, I started getting money in the mail! I was shocked! I figured it would end soon, but the money just kept coming in. In my first week, I made about $25.00. By the end of the second week I had made a total of over $1,000.00! In the third week I had over

$10,000.00 and it's still growing. This is now my fourth week and I have made a total of just over $42,000.00 and it's still coming in rapidly. It's certainly worth $6.00, and 6 stamps, I have spent more than that on the!! Let me tell you how this works and most importantly,

why it works.... Also, make sure you print a copy of this article NOW, so you can get the information off of it as you need it. I promise you that if you follow the directions exactly, that you will start making more money than you thought possible by doing something so easy! Suggestion: Read this entire message carefully! (print it out or download it.) Follow the simple directions and watch the money come in!

It's easy. It's legal. And, your investment is only $6.00 (Plus postage) IMPORTANT: This is not a scam; it is not indecent; it is not illegal; and it is virtually no risk - it really works!!!! If all of the following instructions are adhered to, you will receive extraordinary dividends. PLEASE NOTE: Please follow these directions EXACTLY, and $50,000 or more can be yours in 20 to 60 days. This program remains successful because of the honesty and integrity of the participants. Please continue its success by carefully adhering to the instructions. You will now become part of the Mail Order business. In this business your product is not solid and tangible, it's a service. You are in the business of developing Mailing Lists. Many large corporations are happy to pay big bucks for quality lists. However, the

money made from the mailing lists is secondary to the income which is made from people like you and me asking to be included in that list. Here are the 4 easy steps to success: STEP 1: Get 6 separate pieces of paper and write the following on each piece of paper "PLEASE PUT ME ON YOUR MAILING LIST." Now get 6 US $1.00 bills and place ONE inside EACH of the 6 pieces of paper so the bill will not be seen through the envelope (to prevent thievery). Next, place one paper in each of the 6 envelopes and seal them. You should now have 6 sealed envelopes, each with a piece of paper stating the above phrase, your name and address, and a $1.00 bill. What you are doing is creating a service. THIS IS ABSOLUTELY LEGAL! You are requesting a legitimate service and you are paying for it! Like most of us I was a little skeptical and a little worried about the legal aspects of it all. So I checked it out with the

U.S. Post Office (1-800-725-2161) and they confirmed that it is indeed legal! Mail the 6 envelopes to the following addresses: #1)Dan Warner 2812
W. 1st. St. Duluth, MN 55806 #2) Karen Green 50 Gillinder Street Rockhampton Qld Australia 4700 #3) Ryan Lake 41130 Congerbay Dr Harrison Twp, MI 48045 #4) Zac Inchley unit 82/ 128 Benowa rd Southport

Qld Australia 4215 #5) Carl Baker 2267 N. Kedzie 1st floor Chicago, Illinois 60647 #6) Jason Otto 600 s. 1st st. Waterford, WI 53185
STEP 2: Now take the #1 name off the list that you see
above, move the other names up (6 becomes 5, 5 becomes 4, etc.) and add

YOUR Name as number 6 on the list. STEP 3: Change anything you need to,

but try to keep this article as close to original as possible. Now, post your amended article to at least 200 newsgroups. (I think there are close to 24,000 groups) All you need is 200, but remember, the more

you post, the more money you make! This is perfectly legal! If you have

any doubts, refer to Title 18 Sec. 1302 & 1341 of the Postal laws. Keep

a copy of these steps for yourself and, whenever you need money, you can use it again, and again. NOTE: You may want to retain every name and address sent to you, either on a computer or hard copy and keep the

notes people send you. This VERIFIES that you are truly providing a service. (Also, it might be a good idea to wrap the $1 bill in dark paper to reduce the risk of mail theft.) So, as each post is downloaded

and the directions carefully followed, six members will be reimbursed for their participation as a List Developer with one dollar each. Your name will move up the list geometrically so that when your name reaches

the #1 position you will be receiving thousands of dollars in CASH!!! What an opportunity for only $6.00 ($1.00 for each of the first six people listed above) Send it now, add your own name to the list and you're in business! ---DIRECTIONS ----- FOR HOW TO POST TO NEWSGROUPS---------- Step 1) You do not need to re-type this entire letter to do your own posting. Simply put your cursor at the beginning

of this letter and drag your cursor to the bottom of this document, and

select 'copy' from the edit menu. This will copy the entire letter into

the computer's memory. Step 2) Open a blank 'notepad' file and place your cursor at the top of the blank page. From the 'edit' menu select 'paste'. This will paste a copy of the letter into notepad so that you can add your name to the list. Step 3) Save your new notepad file as a .txt file. If you want to do your postings in different settings, you'll always have this file to go back to. Step 4) Use Netscape or Internet explorer and try searching for various newsgroups (on-line forums, message boards, chat sites, discussions.) Step 5) Visit these message boards and post this article as a new message by highlighting the text of this letter and selecting paste from the edit menu. Fill in

the Subject, this will be the header that everyone sees as they scroll through the list of postings in a particular group, click the post message button. You're done with your first one!
Congratulations...THAT'S IT! All you have to do is jump to different newsgroups and post away, after you get the hang of it, it will take about 30 seconds for each newsgroup! **REMEMBER, THE MORE NEWSGROUPS YOU POST IN, THE MORE MONEY YOU WILL MAKE!! BUT YOU HAVE TO POST A MINIMUM OF 200** That's it! You will begin receiving money from around the world within days! You may eventually want to rent a P.O.Box due to

the large amount of mail you will receive. If you wish to stay anonymous, you can invent a name to use, as long as the postman will deliver it. **JUST MAKE SURE ALL THE ADDRESSES ARE CORRECT. ** Now the WHY part: Out of 200 postings, say I receive only 5 replies (a verylow example). So then I made $5.00 with my name at #6 on the letter. Now, each of the 5 persons who just sent me $1.00 make the MINIMUM 200 postings, each with my name at #5 and only 5 persons respond to each of

the original 5, that is another $25.00 for me, now those 25 each make 200 MINIMUM posts with my name at #4 and only 5 replies each, I will bring in an additional $125.00! Now, those 125 persons turn around and post the MINIMUM 200 with my name at #3 and only receive 5 replies each, I will make an additional $626.00! OK, now here is the fun part, each of those 625 persons post a MINIMUM 200 letters with my name at #2

and they each only receive 5 replies, that just made me $3,125.00!!! Those 3,125 persons will all deliver this message to 200 newsgroups with my name at #1 and if still 5 persons per 200 newsgroups react I will receive $15,625,00! With an original investment of only $6.00! AMAZING! When your name is no longer on the list, you just take the latest posting in the newsgroups, and send out another $6.00 to names on the list, putting your name at number 6 again. And start posting again. The thing to remember is: do you realize that thousands of people all over the world are joining the internet and reading these articles everyday?, JUST LIKE YOU are now!! So, can you afford $6.00 and see if it really works?? I think so... People have said, "what if the plan is played out and no one sends you the money? So what! What

are the chances of that happening when there are tons of new honest users and new honest people who are joining the internet and newsgroups

everyday and are willing to give it a try? Estimates are at 20,000 to 50,000 new users, every day, with thousands of those joining the actual

internet. Remember, play FAIRLY and HONESTLY PLEASE REMEMBER that this program remains successful because of the honesty and integrity of the participants and by their carefully adhering to the directions. Look at

it this way. If you are of integrity, the program will continue and the

money that so many others have received will come your way

3604. Re: Max F/b and max gain at same freq.

Newsgroup: rec.radio.amateur.antenna
Date: 2005-03-11 03:45:47 UTC
From: "aunwin@insightbb.com"
Message-ID: <Lv8Yd.115147$tl3.40640@attbi_s02>
Source record: 80843

O.K. Jim you have my respect so I will go over things again.
I commented that I always thought that it was impossible to have
max gain at the same frequency that one obtained max F/B F/R.
Presumably you read that.

I then stated a theoretical situation where elements worked in pairs but
equal and opposite except
the driven element
You read that I assume
So to draw a "polygon" of the array element phases and current we start with
the driven element,
a vertical line of scalar length and then move on to add a scaler length and
phase to the end of the
director "length.
Hopefully you are still with me

But remember I stated that all other elements were equal and opposite in a
twosome form
to another element, thus even tho we we have gone thru the normal routine we
still arrive at the end
of the driven element scalar line.
Hopefully you are still with me

So to close the scalar diagram we have a line that represents an element
that is in phase
with the director i.e additive. This diagram does not show that the element
pairs are doing
nothing and therefore of no use, those elements still radiate but they
oppose each other
with the final result that to close the diagram an element is required that
has the same
phase and magnitude as the fed element
Still with me I hope

With a single dipole over ground we get a figure 8 radiation pattern
but we have just shown how an array can be theoreticaly formed that
results in a unidirectional form where one part of the figure 8 pattern
has been cancelled and at the same time we have two radiation patterns
on the same side of the feed point in additive fashion in the form of a
perfect circle which is larger than either of the circles formed in the
figure 8
pattern.

Yes a lot of steps in this thought process but stick with me

Looking at the final large circle we can say that the demise of the rear pattern
equates with maximum gain and where the lobe width has become larger
instead of the normal narrowing effect that we get with a Yagi
Still with me?

We can also see that using such an array can avoid the manufacture of side lobes
whether they are frontal or otherwise as our "Polygon" is symetrical where one
made for a yagi is not such that errant reflective rays are created.

To wrap things up: the thread was created because I had created such an array
using NEC with 300 segments per half wave which produced awesome front to
rear figures which some readers questioned the feasability. I also questioned the results
of the model for many months ,UNTIL I came up with the cited analogy
The model matched the analogy tho the pairs of elements were not exactly equal
but very close and the resulting pattern matched the analogy in that it became
LARGER. With two strikes in agreement I then sort for a final crunch mode and that was
to make what is a mechanical difficult array to build as well as expensive for something
that still had lingering questions. The winter has been harsh but with a little time spent
each day during the last six months I now need one half day of good weather without wind
to place this new fangled array at the tower top and without the need of the heavy rotor
(prop pitch) which was needed for its equivalent long boom yagi.(I do this without help
and I am not as strong as I used to be now that I am past 70)
I don't understand the derisve comments regarding my beliefs and the ensueing
experimentation and building except there is a prevailing thought in the U.S.
that it is impossible to discover anything new as every thing possible was already
known, but else where in the world the average ham still experiments to pursue
new knoweledge.
The world is really seen as out of step with the U.S. in more that one way and this
thread portrays just one more thing to add to the list.
Regards
Art..... KB9MZ,,,,,, XG

\
I then illustrated where such an array could be drawn polygon fashion

You read that I assume

So if I understand you correctly (a *really* dubious proposition) I
would have much better success with my 20 meter antenna if I embraced
your philosophy. My current antenna is of my design, a three-element
monoband Yagi-Uda parasitic array. You can see it in the picture on
qrz.com. It is an honest to goodness actual antenna. I have 310
countries confirmed on 20 meters most of them (The hard ones) worked
with this antenna. All at the "too-low" height (according to you) of
45' above ground. I would be delighted to send you an EZNEC,
Multinec, or NEC file that describes the antenna. The model accounts
for boom to mast connection, element taper, etc. (per Leeson,
"Physical Design of Yagi Antennas."), includes the stub matching feed
system and appears to accurately describe the antenna to the best of
my limited capability to measure it.

Over the band of interest, 14.0 to 14.25 MHz., the modeled free-space
FB exceeds 20 dB and the gain varies from ~ 7.9 to 8.15 dBi. The FB
peaks at ~ 14.12 MHz and the gain is maximum at 8.15 dBi at 14.25 MHz.

Pray tell, what operational advantage am I giving up because the gain
at 14.12 MHz (the FB peak) is *only* about 8.0 dBi instead of 8.15
dBi?

MAKE $6,000 TO $30,000 IN JUST A FEW WEEKS!!!
LEARN HOW TO TURN $6 INTO $6000OR EVEN $60000!!
TURN SIX DOLLARS INTO $6000 EASY AND HONESTLY!!!
READING THIS MESSAGE WILL CHANGE YOUR LIFE FOREVER

: I found this on a bulletin board and decided to try it. A little
: while back, I was browsing through newsgroups, just like you are now,

: and came across an article similar to this that said you could make
: thousands of dollars within weeks with only an initial investment of
: $6.00! So I thought, "Yeah right, this must be a scam", but
: like most of us, I was curious, so I kept reading. Anyway, it said
: that you send $1.00 to each of the 6 names and address stated in the
: article. You then place your own name and address in the bottom of
: the list at #6, and post the article in at least 200 newsgroups.
: (There are thousands) No catch, that was it. So after thinking it
: over, and talking to a few people first, I thought about trying it. I

: figured: "what have I got to lose except 6 stamps and $6.00,
: right?" Then I invested the measly $6.00. Well GUESS WHAT!?...
: within 7 days, I started getting money in the mail! I was shocked! I
: figured it would end soon, but the money just kept coming in. In my
: first week, I made about $25.00. By the end of the second week I had
: made a total of over $1,000.00! In the third week I had over
: $10,000.00 and it's still growing. This is now my fourth week and I
: have made a total of just over $42,000.00 and it's still coming in
: rapidly. It's certainly worth $6.00, and 6 stamps, I have spent more
: than that on the lottery!! Let me tell you how this works and most
: importantly, WHY it works... Also, make sure you print a copy of this

: article NOW, so you can get the information off of it as you need it.

: I promise you that if you follow the directions exactly, that you
: will start making more money than you thought possible by doing
: something so easy!

: Suggestion: Read this entire message carefully! (print it out or
: download it.) Follow the simple directions and watch the money come
: in!

: It's easy. It's legal. And, your investment is only $6.00 (Plus
: postage)

: IMPORTANT: This is not a rip-off; it is not indecent; it is not
: ; and it is 99% no risk - it really works!

: If all of the following instructions are adhered to, you will receive

: extraordinary dividends.

: PLEASE NOTE:
: Please follow these directions EXACTLY, and $50,000 or more can be
: yours in 20 to 60 days. This program remains successful because of
: the honesty and integrity of the participants. Please continue its
: success by carefully adhering to the instructions.

: You will now become part of the Mail Order business. In this business

: your product is not solid and tangible, it's a service. You are in
: the business of developing Mailing Lists. Many large corporations are

: happy to pay big bucks for quality lists. However, the money made
: from the mailing lists is secondary to the income which is made from
: people like you and me asking to be included in that list.

: Here are the 4 easy steps to success:

: STEP 1: Get 6 separate pieces of paper and write the following on
: each piece of paper "PLEASE PUT ME ON YOUR MAILING LIST." Now
: get 6 US $1.00 bills and place ONE inside EACH of the 6 pieces of
: paper so the bill will not be seen through the envelope (to prevent
: thievery). Next, place one paper in each of the 6 envelopes and seal
: them. You should now have 6 sealed envelopes, each with a piece of
: paper stating the above phrase, your name and address, and a $1.00
: bill. What you are doing is creating a service. THIS IS ABSOLUTELY
: LEGAL! You are requesting a legitimate service and you are paying for

: it! Like most of us I was a little skeptical and a little worried
: about the legal aspects of it all. So I checked it out with the U.S.
: Post Office (1-800-725-2161) and they confirmed that it is indeed
: legal. Mail the 6 envelopes to the following addresses:
:
: #1) Jeremy Patrick
: P O Box 570632
: Houston, TX 77257
:
: #2) Palak Patel
: 719 Oak Mill Ct
: Addison, IL 60101
:
: #3) Simon Willis
: 4933 Royal Ct. N.
: West Palm Beach, Fl 33415
:
: #4) Alex Martinez
: 2700 Iowa Ave. #9
: Riverside, CA 92507
:
: #5) William Stewart
: 39 Highland Ave.
: Sicklerville, NJ 08081

:
: #6) Roberto Aramburu
: 5933-1 Longstreet Dr.
: Ft Riley, KS 66442
:
: STEP 2: Now take the #1 name off the list that you see above, move
: the other names up 1 place (#2 becomes #1, #3 becomes #2, etc...) and
add YOUR
: name and address as number 6 on the list.
: STEP 3: Change anything you need to, but try to keep this article as
: close to original as possible. Now, post your amended article to at
: least 200 newsgroups. (I think there are close to 24,000 groups) All
: you need is 200, but remember, the more you post, the more money you
: make! You won't get very much unless you post like crazy. :)

: This is perfectly legal! If you have any doubts, refer to Title 18
: Sec. 1302 & 1341 of the Postal lottery laws.
: Keep a copy of these steps for yourself and, whenever you need money,

: you can use it again, and again.

: PLEASE REMEMBER that this program remains successful because of the
: honesty and integrity of the participants and by their carefully
: adhering to the directions. Look at it this way. If you are of
: integrity, the program will continue and the money that so many
: others have received will come your way.

: NOTE: You may want to retain every name and address sent to you,
: either on a computer or hard copy and keep the notes people send you.

: This VERIFIES that you are truly providing a service. (Also, it might

: be a good idea to wrap the $1 bill in dark paper to reduce the risk
: of mail theft.)

: So, as each post is downloaded and the directions carefully followed,

: six members will be reimbursed for their participation as a List
: Developer with one dollar each. Your name will move up the list
: geometrically so that when your name reaches the #1 position you will

: be receiving thousands of dollars in CASH!!! What an opportunity for
: only $6.00 ($1.00 for each of the first six people listed above) Send

: it now, add your own name to the list and you're in business!
---DIRECTIONS ----- FOR HOW TO POST TO NEWSGROUPS------------

: Step 1) You do not need to re-type this entire letter to do your own
: posting. Simply put your cursor at the beginning of this letter and
: drag your cursor to the bottom of this note, and select 'copy'
: from the edit menu. This will copy the entire letter into the
: computer's memory.
: Step 2) Open a blank 'notepad' file and place your cursor at the top
: of the blank page. From the 'edit' menu select 'paste'. This will

: paste a copy of the letter into notepad so that you can add your name

: to the list. Step 3) Save your new notepad file as a .txt file. If
: you want to do your postings in different settings, you'll always
: have this file to go back to.
: Step 4) Use Netscape or Internet explorer and try searching for
: various newsgroups (on-line forums, message boards, chat sites,
: discussions.)
: Step 5) Visit these message boards and post this article as a new
: message by highlighting the text of this letter and selecting paste
: from the edit menu. Fill in the Subject, this will be the header that

: everyone sees as they scroll through the list of postings in a
: particular group, click the post message on. You're done with
: your first one! Congratulations...THAT'S IT! All you have to do is
: jump to different newsgroups and post away, after you get the hang of

: it, it will take about 30 seconds for each newsgroup! **REMEMBER, THE

: MORE NEWSGROUPS YOU POST IN, THE MORE MONEY YOU WILL MAKE! BUT YOU
: HAVE TO POST A MINIMUM OF 200** That's it! You will begin receiving
: money from around the world within days! You may eventually want to
: rent a P.O.Box due to the large amount of mail you will receive. If
: you wish to stay anonymous, you can invent a name to use, as long as
: the postman will deliver it. **JUST MAKE SURE ALL THE ADDRESSES ARE
: CORRECT.**

: Now,
: each of the 5 persons who just sent me $1.00 make the MINIMUM 200
: postings, each with my name at #5 and only 5 persons respond to each
: of the original 5, that is another $25.00 for me, now those 25 each
: make 200 MINIMUM posts with my name at #4 and only 5 replies each, I
: will bring in an additional $125.00! Now, those 125 persons turn
: around and post the MINIMUM 200 with my name at #3 and only receive 5

: replies each, I will make an additional $625.00! OK, now here is the
: fun part, each of those 625 persons post a MINIMUM 200 letters with
: my name at #2 and they each only receive 5 replies, that just made me

: $3,125.00!!! Those 3,125 persons will all deliver this message to 200

: newsgroups with my name at #1 and if still 5 persons per 200
: newsgroups react I will receive $15,625,00! With an original
: investment of only $6.00! AMAZING! When your name is no longer on the

: list, you just take the latest posting in the newsgroups, and send
: out another $6.00 to names on the list, putting your name at number 6

: again. And start posting again. The thing to remember is: do you
: realize that thousands of people all over the world are joining the
: internet and reading these articles everyday?, JUST LIKE YOU are
: now!! So, can you afford $6.00 and see if it really works?? I think
: so... People have said, "what if the plan is played out and no

: one sends you the money? So what! What are the chances of that
: happening when there are tons of new honest users and new honest
: people who are joining the internet and newsgroups everyday and are
: willing to give it a try? Estimates are at 20,000 to 50,000 new
: users, every day, with thousands of those joining the actual
: internet. Remember, play FAIRLY and HONESTLY and this will really:
CHANGE YOUR LIFE!!!
MAKE SURE YOU SEND THE MONEY TO THE SIX ADDRESSES LISTED TO GET
STARTED!!!##

3607. Re: Max F/b and max gain at same freq.

Newsgroup: rec.radio.amateur.antenna
Date: 2005-03-11 05:44:43 UTC

Wes you are off on a tangent again. Go back the the initial posting on this thread.
It says nothing about your poor antenna or even my antenna as I do not have one.
It refers to gain and front to rear at the same frequency It does not refer to an actual physical antenna. None of your postings refer in any sense
can be seen as a technical response that directly refutes the accuracy of what I stated.
In your responces I see nothing but snide remarkes or deviation from the posed subject
by introducing your personal antenna exploits with your own particular antenna
which I say is at an incorrect height. There is nothing in the initiating post that
refers to an actual antenna or even ones that are at an incorrect height.
The true facts behind that initial posting that I had a NEC derived model with extra ordinary back to front figures which made other people suspicious
including me when I posted that info on another thread.
. I was looking for answers to my findings.
This post consisted solely of presenting a theoretical analysis that reflected
the possibility of max gain and max front to rear could appear at the same frequency.
Nobody even tried to challenge the analogy becauuse everybody believes all is known about antennas so there was no point in even to attempt to understand the given analogy. Instead snide remarks were made and diversionary tactics
in changing the subject to actual antennas such as yours.
The subject and question of this thread was made in the hope that technically the analogy
made was incorrect and thus allows me personally to discount the accurracy of my
modelling or on the other hand state they can find no fault with my analogy.
What did I get ? Knee jerk reaction and mirth at the possibility that something new
had possibly been found when all had taken the position that it is safe to debunk
because every thing is known. Not one person itemised a particular line that
gave them particular problems electing to pursue different issues that they have.
and not to respond to the initial request such as you bring up your own

personal
anternna. And remember, in an effort to circumvent this "roast" aproach
I offered to share everything I had with you but you preferred to continue
with
The "roast " aproach. Your antenna and your personal achievements are the
same
as what Roy did when he introduced his past achievements which again does
nothing
to vote pro or con to my theoretical analogy in a technical way.
Don't you realise that other silent viewers around the world are wondering
why the
few are having difficulty with the question. I sure hope that there are
many hams reading
how the so called gurus are dismissing everything other say. Is this the new
way America
feels about those outside of these borders?
Regards
Art....KB9MZ.......XG

3608. Help- loadpole.bas

Newsgroup: rec.radio.amateur.antenna
Date: 2005-03-11 08:24:57 UTC
From: Howard Eisenhauer <howarde@REMOVECAPShfx.eastlink.ca>
Message-ID: <fdj231hmnin7f2sr5sb1rq98mirr4umo8j@4ax.com>
Source record: 80847

I'm trying to decode the math in loadpole.bas (for designing loaded
dipoles) & while some of the formulas are obvious, as a charter member
of the Mathematicaly Declined, I'm getting lost on on most of them
:(.

Heres the section of interest-

```
>+------------------------------ LOADPOLE.BAS -----------------------------ï¿½+-+

>ï¿½2860 LOCATE 10, 30: PRINT " Doing Arithmetic "
>ï¿½2870 LOCATE 12, 30: PRINT " " _
>ï¿½2880 'Arithmetic _
>ï¿½2890 MA# = (10 ^ 6) / (34 * PI# * F) _
>ï¿½2900 MB# = (LOG(((24 * (K / F)) - B) / (D)) - 1) _
>ï¿½2910 MC# = (K / F) - B _
>ï¿½2920 MD# = (((1 - ((F * B) / (K))) ^ 2) - 1) _
>ï¿½2930 ME# = (MB# * MD#) / MC# _
>ï¿½2940 MF# = (LOG((1 / D) * 24 * ((A / 2) - B))) - 1 _
>ï¿½2950 MG# = ((((F * A) / 2) - (F * B)) / K) ^ 2 - 1 _
>ï¿½2960 MH# = ((A / 2) - B) _
>ï¿½2970 MI# = (MF# * MG#) / MH# _
>ï¿½2980 XL# = MA# * (ME# - MI#) _
>ï¿½2990 LUH# = XL# / (2 * PI# * F) _
>ï¿½3000 RETURN: ' End of subroutine _
```

Where:

A= dipole lenght (ft)
B= distance from feed point to the loading coil (ft)
D=conductor diameter (in)
F=Freq (mhz)
K=234 (1/4 w/l ???)
Pi=3.14159 yaddayaddayadda
LUH= load coil inductance
XL= load coil reactance

LUH is easy e'nuff.
MC looks like it's the length of the end sections, but so does MH
MA is looking eerily familiar but that "34" is throwing me off, same
for those "24"s in MB & MD.
Maybe its 'cause its 4 in the morning right now but XL is looking more
& more like Black Magic

I might be able to thrash my way through this after a while but this
is more of a "destination" than a "journey" project, so-

Anyone of the Mathamaticly Inclined here feel like trying to explain to me line by line whats going on here? Feel free to be as pedantic as you want :).

Thanks,

H.

Art Unwin wrote:
"I have just come to realise that if one drew a polygon of element phases in an array and all elements were 180 degrees to its companion element and excluding the driven elemment, the max gain and max front to back will occur at the same frequency!"

Would an antenna made entirely of pairs of identical out of phase elements be a good antenna?

A "polygon of element phases" must refer to the resultant current in each element and their combined effect at a point (P) for example in the far field. Art must have resolved and composed vectors or phasors at some time. The resultant of any number of vectors can all add to zero or to some other number and direction. A zero sum often happens in physics when systems are in equiblirium. Newton said that any action results in an equal and opposite reaction. Application of a new force often causes no loss in equilibrium, just a corresponding added reaction.

The reflected wave from an antenna may change in magnitude in proportion to an incidebt wave yet be nearly exactly equal in magnitude and 180-degrees out of phase with the incident wave, if the reflection is perfect.

A polygon is a closed plane bounded by straight sides. It can represenht forces.

Art asked if there were anything written about complete front to back cancellation in two radiators carrying oppositely directed signals if I understood the question. Indeed Kraus of W8JK fame has a lot to say about the possibility.

Kraus writes about an "Array of Two Driven 1/2-wavelength El;ements. General Case with Equal Currents of Any Phase Relation." in his 1950 edition of "Antennas".

It includes on page 294, field patterns for physical spacings and feed phasings. For example, at a spacing of 1/8-wavelength and a phasing of 135-degrees, there is complete cancellation in one direction while there is maximum radiation in the opposite direction.
That`s the good news. Now the bad.

On page 297 Kraus says:
"However, in the flat-top (an advantage placing all elements at maximum height) antenna such losses may have considerable effect on the gain (as the feedpoint resistance is very low). Therefore, the question of losses and of radiating efficiency will be treated in this section in connection with a discussion of arrays of two closely spaced,

out-of-phase elements. The term "closely-spaced" will be taken to mean that the elements are spaced 1/4 wavelength or less."

Then, Kraus shows another fly in the ointment on page 300:

"Hence the Q for 1/8 wavelength spacing is about four times the Q for 1/4 wavelength spacing. Very large Q indicates a large amount of stored energy near the antenna in proportion to the energy radiated per cycle. This also means that the antenna acts like a sharply tuned circuit."

So much for bandwidth!

Best regards, Richard Harrison, KB5WZI

Richard
So the principle is good tho in Kraus case he used two feeds instead of one.
Doing it his way with just 2 elements makes it very sensirive to frequency
which obviously not a good thing as you point out.
Your post does have my interest as I would like to see what gain he arrived
at by placig all radiation to the front.
In my case the gain just fell short of 16dbi I will look it up in the
antenna books, thanks for pointing that one out
Best regards
Art KB9MZ......XG

Richard
I looked thru The ARRL antenna book and I cannot find
any antenna let alone the two element phased array
that showed ZERO radiation to the rear of the feed point.
Is it possible you are pointing to F/B for minimum radiation
where I am refering to zero front to rear:
Regards
Art

In my ARRL Antenna Book, 15th edition, page 8-6: Two phased
verticals with 1/8WL spacing and phased at 135 degrees shows
a perfect cardioid with zero radiation in a direction 180
degrees from the direction of maximum gain, i.e. directly
to the rear.

Yes Cecil, a cardioid pattern ,which cannot produce zero radiation at the
rear 180 degrees of the feed point.
Remember we started of with a figure 8 or two balloon pattern so for total
reversal of radiation the front lobe
must finish up as a perfect circle . Said another way, the two ballons are
merged thus making a larger single balloon
Best Regards
Art

Art, KB9MZ wrote:
"---I would like to see the gain he arrives at---."

Kraus gives the W8JK close-spaced beam (spacing:1/8-wavelength) a gain of 5.8 dBi on page 552 in his 2002 3rd edition of "Antennas". A dipole in free-space has a gain of 2.14 dB over an isotropic, so the W8JK has a gain of 3.66 dBd. This makes the W8JLK comparable in gain to other 2-element beams in Arnold B. Bailey`s "TV and Other Receiving Antennas" catalog.

I was quoting the patterns in Kraus` 1950 edition of "Antennas" on page 294.

However, there is a measured by D.C. Cleckner of Ohio State University pattern of a 3-element Yagi-Uda with more than 7 dB gain and almost zero radiation in the direction of 180-degrees from the maximum. It is on page 246. This has 0.1-wavelength spacing between elements.

Art,

Why not?

The cardioid pattern from a two-element array was reported back as least as far as 1937, by the famous George H. Brown. In the ideal case (free space, no losses, etc.) the radiation directly to the rear is precisely zero.

If you add various real world effects then the back lobe is not precisely zero, and this is shown in the ARRL Antenna Book referenced by Cecil.

A detailed description of all of this is in Kraus' Antennas, 2nd Ed., in Chapter 11. He uses equations, and he does not mention coordination of balloon patterns, so perhaps you have another new invention.

first described by Johann Castillon made a Fellow of the Royal Society
of London in 1753:
r = 2a(1 + cos(theta))
where theta = 180 such that:
r = 2a(1 + cos(180))
r = 2a(1 + -1)
r = 0

Hi Art,

Understandably, the term you are so unfamiliar with, insofar as no
rearward radiation (not the same as no radiation to 180 degrees) is
Lambertian. As may be expected, the term is derived from the work of
mathematician Johann Heinrich Lambert (1728-1777).

It is a distribution curve derived from reflections off of a "diffuse
surface" (note, not the same thing as reflections off of a specular
antenna element):
(xï¿½+yï¿½+zï¿½)ï¿½ = z

At 300 years+ both are pretty old works that each easily qualify
within the purview of "first principles" if one is serious about
radiation.

Hi Group,
I am planning to place a wire multiband, 50ohm coax feed, based on plans found on Buxcom. His is for 80m and up, I dont have that kind of room so used his formula to generate a 40m and up. My question is about matching the impedence. His 80m uses a 4:1 and assumes placement higher than 20 feet.
I cant get the whole thing over 20 feet, but I can get part of it over 20. The antenna will start off on my roof peak (13 feet tall) then angle out at about 40 deg to a tree.
I cant model this so I have to ask, can I still use the 4:1 or will I need something else?
Thanks for any guidance!!

A 6:1 balun is usually beter for an OCF antenna. They are harder to make
and come by. That is one reason a 4:1 is often used.

Hi Art,

That is the Cartesian form. A 2D polar form would follow:

I = I0 ï¿½ A ï¿½ cos (phi) ï¿½ cos (theta) / Pi
where
I is the intensity at a point with elevation theta
A is the area of the surface
I0 is the radiation directed normal to a diffuse surface
phi is the angle of incidence (all angles being considered)

A variant for conforming radiators is found in:

I = I0 ï¿½ cos (theta)

Observation will reveal why this is called Lambert's Cosine Law.
Simple draughting techniques will reveal the circular distribution
curve.

A simple example of the last equation is found in the common, unlensed
LED. Insofar as radios go, I expect the same response would follow
from placing an isotropic source above a diffuse reflector (you would
then have to use the first equation).

You want zero radiation in an entire hemisphere?
Arecibo probably meets that specification. :-)

Hi Art,

As I said, you are not working in Cartesians in the first place with
"polygons." It is a formula for computer generation of the surface.

If you absolutely need to understand the formula, read through the
code that is used to construct the distribution curve:

```
#define sz 2000000
#define bc 19
static double fr() {return rand()/(double)~(1<<31);}
static double sq(double x){return x*x;}
int hi[bc]; int out=0;
int main(){
{int j=bc; while(j--) hi[j]=0;}
{int j=sz; while(j--) {
double x = fr()*1.4-.7, y=fr()*1.4-.7, z=fr();
if(sq(x*x+y*y+z*z) < z) {
++hi[(int)(z/sqrt(x*x+y*y+z*z)*bc)];}
else ++out;}}
{int j; for(j=0; j<bc; ++j) printf("%d %d %8.2f\n",
j, hi[j], (sz-out)*(j+.5)/(bc*bc/2));}
printf ("%d out of box.\n", out);
}
```

If you still don't understand, the polar coordinate formulas are just
as useful, simpler, and take very little work to construct a "polygon"
that obtains complete closure. It is, after all, a construction much
like any of a number of classic curves. You need only conform to the
requirements of a Lambertian surface or emitter to obtain the curve
you describe.

Hi Dave,

You should find that the antenna will work well for you except perhaps on 15m I have a very similar set up here and it works great.. Unlike he says on the Buxcom site though you will most likely need a choke balun 1:1 in the line to keep RF out of the Shack, Mine is similar to the Carolina Windom in that I placed a Choke balun about 30 feet down the feed line .. works quite well..

Hi all,

I have an "old" W-8010 Diamond antenna that don't use anymore.
Everything is in very good condition.

I would like to transform this antenna into a W-735.

This means that I would like to take my BU-50 balloon and the two 80m
traps from my W-8010 and make an antenna just for 40 and 80 meters.

Would like to know if any of you guys know if this is possible, and if
so, what would be the size (length) of the wires.
Also, would like to know if the 80m traps are the same.

Any help is much apreciated.
Best Regards,

Andre Antunes

I have built an antenna analyzer (AA-908) that reports SWR, complex impedance, capacitance and inductance. It works fine with coax-fed resonant antennas.

How can I use it to test a 40M double zepp with 300 ohm twinlead feedline? I am at this point interested in finding the frequencies in 160M band at which this antenna and particular-length feedline will propagate.

Needless to say, I see maxed out numbers almost all the time (SWR>10 and impedance >600). Should I use a balun? Is there something I can use (like a 50 ohm resistor in parallel) that will give me numbers that I can use? What should I be looking for?

a 10:1 balun would probably help get readings down into a range that your analyzer can handle, assuming the >600 ohms is the real impedance.

A 40m double Zepp is 1/2WL on 80m. You didn't say how long the
feedline is. You can get a ballpark idea of the impedance by
downloading the free demo version of EZNEC from www.eznec.com.

Assuming the dipole is 130 ft. long, EZNEC says the antenna
system can be resonated by a feedline length of 96 ft. using
300 ohm line with a VF = 0.9. The impedance seen looking into
the feedline is 0.7 ohms. EZNEC says the antenna has a feedpoint
impedance of 9.3-j1060 on 1.9 MHz with a sky high SWR on the
300 ohm line. This antenna will perform poorly on 160m.

A better solution for 160m would be to short the parallel
feedline together at the tuner and feed the whole thing against
ground, aka Marconi style, with the 40m double Zepp acting as
a top hat.

Ken

I consider dave,s suggestion to build a good transformer to be the best
way to estimate antenna impedance that is beyond the range of your meter.

Is a Smith Chart something you'd use? I cant say which method is best
for your use. But, I'd try estimating the antenna's impedance by
translating back toward the radiator with the assumption that you know. It
is necessary to know the *impedance*, not just the VSWR on the 50 ohm line.
Then, make an attempt to improve the antenna's impedance and see if your
assumptions are appropriate by re-measuring the impedance that results on
the 50 ohm line.

Jerry

3649. EZNEC Model of 88ft doublet

Newsgroup: rec.radio.amateur.antenna
Date: 2005-03-12 22:18:08 UTC
From: Jim Miller <jim@jtmiller.com>
Message-ID: <1110665888.643793.123700@z14g2000cwz.googlegroups.com>
Source record: 80788

I downloaded the demo of EZNEC4 to see what it would show for a 88ft doublet 50ft in the air fed by 300ohm twinlead.

My model has two wires each 44ft long joined in the middle at 50ft elevation with another wire pair 0.1ft long 0.1ft of elevation.

They are joined by two 300ohm transmission lines and a split current source is placed at the 0.1 elevation junction.

When I run the SWR plot it shows over 100:1 with minima near 2:1 at 6.5Mhz and 11.75Mhz.

Does this sound about right or am I not modeling it correctly?

tnx

I agree with Torsten. You need make no changes to your present run of cables (along a messenger cable) other than adding clamp-on chokes to each wire (including the messenger cable). If the "run" is a significant part of 0.25 WL at a frequency of concern, you may find it desirable to place a second set of clamp-on-chokes about 0.25 WL from the first set or near the house entrance (whichever comes first).

You will need radials in order to have reasonable efficiency. An impedance bridge will help in finding the connection spot on the tower where the real part of Z is 50 (or 70) ohms.

Let us know what you do.

You don't need two transmission lines for balanced
line. The dipole can be just one wire with the
single 300 ohm transmission line attached at the
50% point.

Hi Jim, The 6.5 Mhz SWR sounds about right, the 11.75Mhz does not.
What are you trying to do, an exercise in modeling, or a specific
antenna and transmission line for a specific band?
This is just me, but for complete antenna systems, I use EZNEC for
the antenna input Impedance, and other stuff for the transmission lines
and matching networks.

Hi Cecil, I think he is refering to the way you model a non-radiating
transmission line. It is simply two wires, not two 300 ohm lines
attached to the 50% point.

OK, at cecil's suggestion I changed to a single 20 segment wire with a split I source at 50%. I ran the SWR plot against a 300ohm alternate impedence. Is that the way to see what effect a 300ohm twinlead will have? Now I get a minimum 2:1 SWR at 5.6Mhz and a pretty smooth convex curve out from there to 14.5Mhz with a max SWR along that leg of around 35 at 12.1Mhz.

3657. Yagi Hairpin Match

Newsgroup: rec.radio.amateur.antenna
Date: 2005-03-13 00:46:04 UTC
From: muskie <muskie@muskie.com>
Message-ID: <d10431$2uah$2@news.hgc.com.hk>
Source record: 80796

I'm a newbie in HAM and would like to build my own 430mhz 3 elements Yagi but don't have enough information. Although I have the ARRL Handbook and ARRL Antenna book. But, I do have some questions about that.

1. Detail information about the hairpin. match (i.e. length, the distance between the 2 legs and the location to solder)

2. The feedline should be even or odd 1/4 wavelength?

3. When solder the feedline to the hairpin, what's the location?

4. If I don't have the SWR meter, is it still possible to build the Yagi?

I did the search for a month on the net and newsgroup, but still don't have any luck to give me the answers. Thanks for any comment in advance!!!

Hi OM,

You should have some form of a design in front of you, even if it is a
copy of an advertising brochure to work from. At this scale, it is
pretty simple to build a working model, but first observe the answer
to question 4 below.

>2. The feedline should be even or odd 1/4 wavelength?

If you did your matching right (this is the answer to question 3), it
won't matter. However, you cannot tell if you did the matching right
until you get to question 4 below.

>3. When solder the feedline to the hairpin, what's the location?

This is one of those variables that you determine when all else is
done. As such it requires a SWR meter (see how these issues cascade
to your tools?).

>4. If I don't have the SWR meter, is it still possible to build the Yagi?

With as much cut-and-try, you need more tools than a screwdriver and
pliers. Building to a scaled model only goes so far when you have to
actually perform a sanity check. The SWR meter will tell you how well
the design matches to the power transfer from a transmitter, a notable
performance variable, but not the only one.

>I did the search for a month on the net and newsgroup, but still don't have
>any luck to give me the answers. Thanks for any comment in advance!!!

When you build your own, each construction is its own masterpiece.
The only way to guarantee performance is to build an identical copy.
You can buy a model, but then you wouldn't need to build one after
that.... There's as many models as there are characteristics that you
want to optimize. So, you have to FIRST determine, what
characteristics are important, THEN find the model (or build one in
software, then in copper, then one that is weatherproof).

The simple resolution is to invest in tools and expect to go through
at least a couple or three designs. That is, for a yagi style. There
are simpler designs that work the first time - but you didn't ask THAT
question.

3659. Mostly horizontal polarization of HF arriving at my antenna?

Newsgroup: rec.radio.amateur.antenna
Date: 2005-03-13 02:55:27 UTC
From: tf3kx@simnet.is
Message-ID: <cc4f4620.0503121855.151a414a@posting.google.com>
Source record: 80798

I have an inverted-V, approximately resonant on 40, 20, 15 and 10m.

I have tried numerous verticals for comparison, but on these bands the inverted-V always receives signals on these bands better or equally well, at best. The verticals have been well grounded (using a "large, good quality" metal sheet roof as the ground) and I have done my best to minimize losses. The verticals have been anywhere from 1/4 to 5/8 wavelengths long. But they are always outperformed by my inv-V on these bands. Only on 80 and 160m are the verticals better.

Now, this leads me to wondering if the radio waves arriving at my QTH tend to be largely horizontally polarized on the higher frequencies? Or can there be any other explanation that "good" verticals, even 5/8 wavelengths long are never better than the inv-V. Any thoughts?

The verticals and the inv-V were all mounted on the metal roof of my house. The house is located in a poor-quality ground area (rocks, shallow vegetation), the direction to Europe is across a low hill approx. 1/2 mile away while the direction to America is across the open sea approx. 1/8 mile away from my house.

I had a wilson 4 band verticle mounted on top of a 30 foot tower with
4 radials run out for each band, in short if I could hear 'em I could work
'em. It was that simple........ Noise seems to be more pronounced with
verticle polarization. I did have a 40M inverted vee on that tower as well
and used to switch between the antennas. Since I was on the west coast at
the time, the east coasters were stronger on the verticle than the inverted
vee. I would in NO way say my tests were very scientific, just looked at the
S meter readings. Yes it was an actual meter movement (IC-720) had one. I
hope this helps you in some way with what you are trying to accomplish.

That's more like it and you don't need a split-I source in the
middle of one wire. Split-I sources are used at the intersection
of two wires. 492/88' = 5.6 MHz. 984/88' = 11.2 MHz.

For 7 MHz and up, this antenna would be better behaved with 450
ohm ladder-line or open wire line. The best Z0 for the feedline
is Sqrt(Rmin*Rmax) ~ Sqrt(50*7000) ~ 600 ohms.

Source record: 80803

I see in chap. 19 of my 19th ed. ARRL Antenna Handbook a description of a quadrifilar balun transformer with taps at 16:1, 9:1, 6:1 and 4:1.

Is such a balun sold commercially?

If I homebrew it, how do I know where to put the three lower-ratio taps? Inasmuch as the taps are usually made by putting a small loop in the magnet wire, this can't be done after the winding is done.

Hi Cecil

Thanks for your help. Looks like I've got a tiger by the tail. I'm currently using #26awg fed by 300ohm ladderline to minimize visibility. Both contribute to pushing the SWR higher across the spectrum. If I'm not able to get the tuner to match this setup I'll try the 450 ladder and and 18awg and risk the visibility. Actually I've gotten the antenna higher than I thought I would be able to and the 18awg would probably be ok. The ladder line is a bit more difficult to deal with at twice the width unless I can disguise it or hide it behind a tree trunk. Then there is still the issue of providing a guard against kids messing with it.

I'm going to take a multimeter to some white and grey pvc conduit today to see if I can detect any difference in conductivity as some have speculated the grey was more conductive. Which ever I chose I'll have to do some camoflage painting but if the resistance is high and comparable for both I'll select the smallest diameter which allows the ladderline to pass through without cramping.

The hardest part of all of this was getting the halyards up and that's now done. Changing wires isn't a big deal as long as adequate performance and visibility can be balanced.

tnx
jtm

Dear Ken,

Here's something else to keep in mind. Your new instrument is designed and calibrated for use on 50 ohm transmission line. Even if your 300 ohm twinlead were matched properly to an antenna, and there are no standing waves on the line, your instrument will still show an SWR of 6:1

If the product was built in the USA the price would be so High you
would not purchase it.

Would you really pay %500 more for the same product just to have Made
in USA stamped on it? We always look for the bargain price and that
usually means foreign produced products.

Moving production to Mexico where manufacturing cost are lower allows
Amphenol to remain in business.

These days Mexico is being undersold by China where the cost are less than
that of Mexico.

3670. Little help....choke position

Newsgroup: rec.radio.amateur.antenna
Date: 2005-03-13 15:12:07 UTC
From: Ken Bessler <kg0wx@NOSPAMyahoo.com>
Message-ID: <eLYYd.10639$Fy.2243@okepread04>
Source record: 80810

My upper band antenna is a Van Gordon "All Bander". It started out life as a 134' dipole fed with 100' of 450 ohm ladder line. I cut half the ladder line and installed a PL-259 on the end.

My feedline going to it is a length of rg-58 coax with the end being a coil of 12 turns wound around a CD case. The turns were wound, glued then the case was removed, leaving a perfect air coil.

I later trimmed the antenna so it has a low SWR at 7.18 mhz and it works fine.

Now to the issue - yesterday I bought a LDG AT-100 PRO autotuner with the idea that I could tune my 40m antenna to the upper bands. It works but if I tune or operate higher than 85w on 10m FM, the tuner erratically flashes it's SWR bargraph and if I push it further, locks up. Powering the tuner off and on again fixes it (unless I push my luck again).

I've got a good ground but it's 25' away. I'm hooked up to it with braid and 12 awg wire. All station equipment is tied with braid to a central point where the 12 awg wire starts.

I was wondering what would happen if I removed the coax running to my choke? There is enough ladder line to reach. Maybe I should buy a LDG balun and eliminate the coax completley? I would think that would cause more problems as I would have ladder line in the shack?

I tried disconnecting the ground to the tuner and re routing the tuner's power cord with no real resolution of the problem.

Help?

BS!

There are connector houses who assemble in the US on custom order
and they are no more expensive than the assembled in Mexico parts.

Amphenol went to Mexico to get away from the union that was
breaking their back!

3678. Re: Is PVC pipe UV resistant?

Newsgroup: rec.radio.amateur.antenna
Date: 2005-03-13 16:52:49 UTC
From: RST Engineering <jim@rstengineering.com>
Message-ID: <1138rvh4g720pb6@corp.supernews.com>
Source record: 80817

"resistant" is hard to define. I have a j-pole made out of PVC that has been on the roof for almost thirty years. I suppose at some time it will fail, but probably not in my lifetime. I certainly wouldn't expect it to have the same pressure and burst characteristics if I was using it with water pressure, but it seems to hold up well as an antenna structure.

My company has been making vertical dipoles using Schedule 40 PVC as the "radome" for nearly twenty years, and as yet, not a single reported field failure.

Yes, I would. I have witnessed, firsthand, the result of not reinvesting in our own infrastructure. We've recently watched and entire IT department eliminated and their tasks exported offshore. Some dismiss it as "sound business practice," yet choose to remain ignorant of the bigger picture because that would interfere with their own career aspirations. Increasing "the bottom line" is viewed as a feather in one's cap, no matter what means are used to effect this end.

> Would you really pay %500 more for the same product just to have Made
> in USA stamped on it?

You betcha! My rigs are Ten-Tec and Elecraft, not Yaesu, Icom, Alinco, or Kenwood. My keys/paddles are Vibroplex, Bencher, March, or KG2ED, not GHD or Hi-Mound. Why? Because, despite the misconception of some, the quality is comparible and there is an additional sense of satisfaction that my money may be making onto the dinner table of John and/or Jane Doe in the USA as opposed to going offshore. Call it patriotic reinvestment.

> We always look for the bargain price and that
> usually means foreign produced products.

A bargain price is not always a bargain. What if your son or daughter worked at Ford or GM and lost his/her job because the Toyota Camry sold for $3,500.00 less than a Taurus or Impala; Would that Camry you bought as a retirement gift to yourself still seem like such a bargain?

This may be somewhat of an extreme example as $3,500.00 can be a real problem for many folk's budgets, but there are plenty of much smaller things folks can do to send corporate America the message; "If you export our jobs, we will not patronize you business."

Indifference is a real killer.

> Moving production to Mexico where manufacturing cost are lower allows
> Amphenol to remain in business.

I returned mine and bought J&I instead. The quality is just fine and they're made in New Jersey.

How does the hole mount compare to the lip-mount that is well
grounded?

I don't really want to drill a hole in my roof, but I want to get off
the magnet and a lipmount on my hatch will leave the antenna at
roof-top level.

3681. Re: Mostly horizontal polarization of HF arriving at my antenna?

Newsgroup: rec.radio.amateur.antenna
Date: 2005-03-13 18:41:07 UTC
From: TOM <noname@noprovider.nodomain>
Message-ID: <7P%Yd.1796$oa6.1254@trnddc07>
Source record: 80820

HF signals are usually not predominantly polarized more horizontal or
vertical.

The effect that you are seeing is due to the effective height of the dipole
above ground. On 40,20,15,10 the dipole is high enough (in terms of
wavelengths)
that it develops a good pattern at lower angles of radiation (or reception).

On 80 and 160 meters, your dipole is too close to the ground for it to have
a
good low-angle pattern.

Thus what you are seeing is that the signals you want to listen to are
arriving
at an angle lower than what your 80/160 meter dipoles are effective at. The
vertical
antenna has a lower angle of reception on these bands than the dipole.

If you listen to signals out to ~300 km on 80 meters, you may find that your
dipole
outperforms the vertical because those signals are arriving at your antenna
from a
fairly high angle.

The diameter of the wire will make almost no differance. If the antenna is up high enough you may be able to drop the ends some to gain more electrical length.

Thicker wire yields wider band width but does not affect wavelength.

As soon as you bring it down to AZ. I have a 120' run of 2" grey PVC
from the house to the tower. It's mostly above ground with a stake
and clamp every 10'. It looks like a snake, the top side turns color
and it's cracked in a couple of places.

Increasing the wire diameter will not make slightest detectable difference in performance.

But if for some reason you think an increase in length will be beneficial, as it usually is for short antennas, then increase length by extending and bending the ends by about 90 degrees in either the horizontal or vertical directions.

You can extend one or both of the ends down to insulated ground level.

You can extend the ends sideways for as long as you can manage it without any noticeable difference in performance from the whole length being in a straight line. Perhaps the most important characteristic of the antenna, if it is to remain balanced, is that the feedline should be attached approximately at the centre of the overall length. But it's not critical.

There is no doubt that increasing the overall length of a dipole, by whatever means, up to the overall length of 1/3-wavelengths at the lowest frequency of interest, will improve performance. Particularly in transmitting, multiband applications.

I agree with your basic point, but but both the Camry and Sienna
are made in Toyota plants inside the U.S.A., I believe. I just made a net
run looking into this and saw in one netsite information claiming
at least 50% of the Toyotas sold in the US were built in the US. I also
suspect that a lot of Ford and GMC auto parts are not US made. I'd rather it
did not, but the worlds economy constantly mutates and workforces must
change also. We badly need to keep
some seed industries inside the nation, though, just in case we get into
wartime supply difficulties.

Perhaps a little wider bandwidth, would probably require a lot more diameter to achieve much. Not an area of expertise for me, but I have read that bending dipoles is not always a bad thing. You might try adding wire perpendicular to your dipole ends. Also an inverted vee might allow some additional length along the 45 degree downward angle, I believe it might also help with impedance matching (or so I've read).

Thanks for your reply, your point is well taken. I still believe in the basic concept though. I may be somewhat naive, but I believe WE, the consumer, can have a much bigger influence on the world's economy; and thus make it better for WE, the workforce. Sadly, many choose to do nothing and proclaim that the situation is "beyond their control." Then they chortle at the great buy they got at Wal-marts while the mom & pop stores on Main St. close.

Indifference is a killer.

Can't tell what you are trying to say.
I live in California in an area where we get 70 to 90 MPH winds several times a year, sometimes the (water proof) PVC gets rained on, but not much (11 to 36 inches a year. Sun for about 325 Days a year. Still see no damage of any sort. I do not however expect it to last forever, but then neither will I!

BTW: the antenna is Aluminum wire and the water would not damage it either, but then I can't hang the wire out in the wind! It is just several strands of #15 electric fence wire. (Four per element.)

That is not schedule 40 and I did not use the light irrigation pipe. I have been in Arizona (for 29 years) and can not say I ever used PVC for anything. I used Galvanized pipe for sprinklers too. But that was about thirty years ago and before.

I However we had a pool heater from the black flex pipe which lasted for many years. It is no good for RF though!

3696. EZ NEC trouble

Newsgroup: rec.radio.amateur.antenna
Date: 2005-03-14 04:24:26 UTC
From: Scott M <spamsmasher@comcast.net>
Message-ID: <8tadnaj4wpmwj6jfRVn-tg@comcast.com>
Source record: 80735

I have been trying to learn how to use EZNEC. I got the (fully functional) demo version and began the tutorial in the help file to learn how to use the software. I opened the dipole file and tried to change the frequency but when I click in the frequency field, nothing happens and I can't modify anything. I uninstalled, re-downloaded, and re-installed the software. Same problem.

Has anyone else experienced this with EZNEC? Any ideas?

3697. Re: Max F/b and max gain at same freq.

Actually, this isn't quite true. If you manage to get perfectly phased and equal magnitude currents in two identical elements where the phase angle equals 180 degrees minus the element spacing (such as the classic 90-degree fed, 90-degree spaced cardioid), you don't get an infinite front-back ratio. In the case of the cardioid with typical diameter quarter wavelength elements, you end up with around a 35 dB front/back ratio. With longer elements, close to a half wavelength, the front/back ratio can deteriorate to less than 10 dB when base currents are identical in magnitude and correctly phased. The reason is that the mutual coupling between elements alters the current distribution on the elements. The mutual coupling from element 1 to element 2 isn't the same as the coupling from element 2 to element 1 (the mutual Z is the same, but the coupled voltage and coupled impedance aren't). The net result is that the two elements have different current distributions, so despite having identical magnitude base currents the two elements don't generate equal magnitude fields. The overall fields from the two elements end up being imperfectly phased, also.

This occurs for theoretically perfect and perfectly fed elements, and isn't due to "real world" effects.

I published some comments about this effect in "Technical Correspondence" in July 1990 QST ("The Impact of Current Distribution on Array Patterns"). I'm certainly not the first to have observed it -- some papers published as early as the '40s are referenced in my article. But I had never seen its effect on front/back ratio of cardioids mentioned before. Modern versions of the ARRL Antenna Book clearly show the small reverse lobe of a typical antenna with quarter wavelength elements.

I stumbled across it when doing some modeling with ELNEC, the predecessor of EZNEC, and originally thought it was an error in the program. You'll see it in a plot from the Cardioid.EZ EZNEC example file (which is also included with the demo program), and a brief explanation in the corresponding Antenna Notes file.

A theoretically infinite front/back ratio can be achieved by modification of the base currents. The amount of modification required depends on the length and diameter of the elements. Only a small modification is needed if elements are a quarter wavelength high and small diameter, but in that case, real world effects will probably have at least as much and likely more of an effect on the front/back than the current distribution phenomenon. Rather drastic modification is required of the base currents of elements approaching a half wavelength high, however, as elaborated in the "Technical Correspondence" piece.

3700. Re: Mostly horizontal polarization of HF arriving at my antenna?

Newsgroup: rec.radio.amateur.antenna
Date: 2005-03-14 08:47:11 UTC
From: tf3kx@simnet.is
Message-ID: <cc4f4620.0503140047.6abb0d78@posting.google.com>
Source record: 80739

Tom: I agree with you on the 160/80m explanation for the better performance of the vertical than the inv-V.

Generally it is assumed that polarization of arriving HF signals is randomly oriented and constantly changing - which I have no grounds to refute. Thus, your suggestion that my inv-V (horizontal antenna) is simply gaining advantage from its height (and in some cases azimuthal directivity) is a viable explanation. Keep in mind that the inv-V is supported by an aluminum pole with an apex 6m (18ft) above my metallic roof, and the roof itself is at 8m (24ft) above the surrounding ground - thus the apex point is at 14m (42ft) above ground.

It just struck me that even the "supposedly best" verticals (5/8 wl, using good connections to the metal roof as a counterpoise) are consistently substantially weaker on reception on 40-10m than the inv-V. The difference varies from zero to 7-8 S-units. I would have expected the vertical to be better in at least a few cases - but it's not.

But, OK - the inv-V dipole is gaining further from its height. Any other suggestions, anyone?

From: Gary
Message-ID: <4soa3117spb2rk1u5sb3clbo9jo77n5qda@4ax.com>
Source record: 80740

I will have enough problems getting a G5RV erected so I'd just as soon buy a commercail unit. Does anyone have a source for a heavy duty G5RV with a current balun as I'll be feeding it with RG8X from my shack. Running ladder line ot twin lead from my shack and staying away from metal objects (other coax, aluminum siding etc) would be most diffictult.

Thanks in advance.

3702. Single wire aerial - what do I do?

Newsgroup: rec.radio.amateur.antenna
Date: 2005-03-14 14:16:32 UTC
From: (unknown)
Message-ID: <42359ae8.17334672@news.dial.pipex.com>
Source record: 80741

A supid question from someone who thought he knew a bit about electronics...

I've bought a mini hi-fi to place permanently in the kitchen but the FM reception is bad and I want to treat it to an aerial in the loft. The issues are:

- The FM radio only has a short single wire for an aerial, no coax socket.
- The transmission cable will have to run up a duct that's full of mains wiring
- It also runs close to the computer upstairs, which emits interference

My intention was to run coax cable up the duct, hitched to a four-element (or thereabouts) aerial in the loft. But now I'm totally confused by ribbons, coax, baluns, impedence (not stated by the manufacturer) and all the other trappings of this science.

Questions:

Trawling the net, some pundits suggest twin flat ribbon as a simple solution. But surely the stuff is unscreened and will be highly susceptible to stray radiation, reflections etc if I run it up the duct? Am I right in thinking that, with coax cable, the "outer" acts as a shield to the signal running through the "inner"?

Every configuration, whether it's ribbon or coax, ends up with two conductors. Where does the second one go in the absence of a proper socket? To earth / chassis / nowhere? (There's also a socket for an AM coiled aerial, if that helps).

Signal strength in our area is fairly weak but does improve with height. All I want is to boost the signal on main national (UK) stations to an acceptable level for stereo.

At the moment I have a length of Twin & Earth lighting cable running up the duct - we used it as a dummy just to get something fed through (nightmare job!). Don't suppose this will be any use? I was half hoping that this cable, running about 15ft vertically, might in itself provide enough extra signal, but attaching it to the radio's aerial improves things only a little.. We could always use it to pull through a proprietory cable.

Help please. I don't know where to start - especially with the single wire issue. I was hoping to rig up something functional without a lot

of coils and calculations!

Thanks
Paul

3703. 5/8 wave 2 meter antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2005-03-14 14:26:57 UTC

Source record: 80742

Can anyone point me to a good site for construction a 5/8 wave 2M antenna???

I tried home-brewing one already with poor results .... a conductor up a
piece of PVC .... same conductor wound into a coil at the bottome
connected in series to the center of the coax. 4 1/4 wave radials
connected to outer conductor.

Thanks,

--> Rob

Hi Roy,

I have read many of your articles, and I have no doubt you are correct.

However, in the ideal case, specifically in the limit as the wire diameter goes to zero, the current perturbation from mutual inductance vanishes. (The mutual inductance does not vanish, only its impact on current distribution.)

I just spent a few minutes playing around with EZNEC 3, and I was able to achieve a null of -52 dBi (-57 dBmax) for two half-wave elements, with nominal 90 degree spacing and 90 degree phasing. The wire size was as small as possible. This null was in the symmetry plane and directly in the anti-end-fire direction of course. I expect with more computational precision, and perhaps fine tuning frequencies and dimensions this null could be driven farther. The reported current imbalance was a maximum of 0.2%, mid-way between the center and the ends of the wires. The phase imbalance between the wires was a maximum of 0.2 degrees.

I am not trying to say this is practical. I was just pointing out the Art's use of polygons and canceling phasors was not particularly unique.

We have since learned that what Art is trying to accomplish is to eliminate all radiation in the back hemisphere. The cardioid example is obviously moot for his quest.

73,
Gene

I don't believe that there are many, if any, cars that are made in
____ anymore. I think they are all international.

Back to the issue, as to the foreign owned companies in the USA, while
some of their money is being fed back to the locals, the majority of
the money goes overseas to their bank accounts or other foreign
purchases.

Unfortunately, there is no easy solution that won't hurt someone here
in the US. Tariffs would raise our cost of living something terrible,
blocking imports will cause a higher demand in relationship to supply
causing another price increase. Instead of profit sharing, union
workers want higher wages.

There is no easy solution. What helps one group will certainly hurt
another.

Gene,
At a matter of interest during the 80s I tried to get to zero
radiation at 180 degree point
since Lawson stated it was possible. After covering the half acre under the
long boom
with a ground screen, in fraustration, I finally gave up
with the pursuit. On one of my present models the rear radiation never
exceed 40db
for more than 180 degrees but as Roy pointed out earlier you still have to
deal with
the higher angles which was the case with my model in that when the angle
reached
30 degrees elevation we were back to 20 db..
The center "plume" radiation seems difficult to eradicate.
I think I will try your suggetion of radiators with radiators
of 0.01 diameter to see what happens
Regards
Art

"WE the consumer" earning $100,000 per year with two incomes can
afford to spend $40,000 on an automobile or $500 per month on
groceries, but "WE the consumer" earning $12,000 per year has to be
more froogle. By the time they spend $5-600 on housing, they don't
have the money to spend an extra $50/week on groceries just to keep
mom-and-pop corner store in business.

I don't disagree with you, it's a sad situation. There isn't an easy
answer. It is very hard to find things made in the USA anymore.

Hi Kristinn,

It is rather simplistic to describe the inverted V as being a Horizontal antenna. It has a significant Horizontal preference, yes, but only broadside (and there subtends perhaps only a third of the antenna's total response). It also has a minor Vertical preference over the Horizontal response for a third of the total field along the antenna's axis. For the remaining third of the total field, the inverted V is roughly equal in Horizontal and Vertical response.

Source record: 80755

Got a great answer from someone who perhaps preferred to be anonymous:

There is no problem coiling up excess coax. As long as you don't coil it too tight. There is a 6" minimum bend radius for RG-8 size cable. The inductance thing is something someone got garbled. Coiling it up will create inductance for signals flowing on the outside of the coax. This is called a choke balun and is commonly used at the feed point of the antenna. It has no effect, other than the length of the cable adds a little loss, to the desired signal that is flowing on the inside of the cable. Remember in coax the desired signal flows between the inside of the shield braid and center conductor. Any signal flowing on the outside of the coax has no use and may be undesirable. This is why you can tape coax to masts and bury it underground with no effect on the signal. On 80m there is not always a reason to cut the cable just long enough to reach, but on VHF/UHF excess length just means more loss in the coax and is not desirable. Also if you have a lot of extra coax coiled up and you are using a tuner to say make the 80m dipole work on 30m the extra length could cost you something. For example I use my 160/80/40/30 dipole array on 60m (5MHz) band. The Z of the antenna is something like 388-j1200ohms. This high SWR increases the loss in my coax by allot on 60m. In fact the loss is 7.5db. This means my 100 watt is reduced to 18 watts at the antenna. If my feed line was shorter the loss would be less of course. So in this case if I had a lot of extra feed line, short[en!]ing it could really improve my signal strength.

On Mon, 14 Mar 2005 11:00:52 -0500, Buck <iam@this.site> wrote:
>Instead of profit sharing, union workers want higher wages.

Hi Buck,

[not specifically to you, but in the tenor of a St. Helens steam vent]

One has to ask where's the profit to share when the CEO is raping the shareholder? Look at the trial of Bernie Ebbers and the Legally Blonde Defense that is becoming the rage along Wall Street:

"I don't, to this day, know technology. I don't know finance and accounting.

"The closest thing I've ever had to an accounting course is a preliminary course in economics."

In school, it appears he shopped around for a degree because, as he admits:
"...my marks weren't too good."

In his defense, associates would comment:

"...when it came to the numbers. He didn't understand them."

"...anytime we got too far into the details, you could tell we were speaking right past him."

Bernie is not unique. The Titans of industry are all quite willing to step up to the plate and buckle at the knees to declare they are not fit to understand their industry, but that they were hired to be life skills coaches. Talk about gutless. These are the Monoliths of commerce that have plowed the auto industry into their wallets to leave rust behind.

There several hundred major companies that have restated their gains into losses. Every one of these companies paid bonuses for phony performance, bonuses their Boardroom buddies have absolutely refused to recapture in light of fraud and mismanagement. Talk about gutless.

What unions have failed to do is to become shareholders and members of the Board in lieu of assured contracts. Talk about gutless.

No one ever speaks of guts and government in the same breath. Confirming this, the American way of life is now slipping beneath the waves of international inflation. The Dollar is still dropping to the subdued cheer of the administration. They are talking about doubling the social security loss to support two systems, with each clipped

back to "save costs."

We live in a $20 TRILLION dollar economy, with the total tax bite of $3.5 TRILLION and across the board americans (deservedly lower case) are whining about having the burden of a 17.5% rate. I am quite sure most of you reading this are sure you pay far more. But how motivated are you to demand what is simply average? How many are motivated with profit sharing to pay a necessary share to really invest in America? Talk about gutless.

> fair-sized loop out there.

Ok, further to this. Even if I'm not to care about impedance matching or choking, my receiver has an unbalanced antenna input. One side of the antenna connection simply goes to "chassis" ground.

This implies that I should use a traditional BalUn to make the balance connection work for me. Otherwise, one side of a dipole or looped longwire is just going to go straight to ground (such as it is.)

I built myself a reasonably stealthy random-wire running along the top of my wooden balcony railing (which turns a 90-deg corner around the building) for a total length of around 25-30 ft. I was considering simply looping the wire to make a bent, untuned, "folded dipole" (the wires would be 5-6 inches apart) just to get more wire into the wind.

To realize this, I am supposing I'll have to use a true BalUn to get the signal into my unbalanced front-end somehow. Since most designs for a true BalUn assumes I have a decent ground, I'm a bit stumped by your comment. Perhaps the ground of the BalUn can just go to the coax sleeve?

Thanks for all your suggestions.

Hi Paul

Yes it looks like you have a real problem here..

- Yes running ribbon up a power duct is not a good idea. Generally speaking ribbon is pretty good in rejecting noise when there is it least a few inches of air spacing between it and metal objects. The nature of ribbon (or balanced feeder) is that any noise induced in one wire will also appear in the other and they will add out of phase in the receiver.

- Yes coax is a better idea, but be aware that the length of coax will also receive in its own right if both the radio and antenna ends arent terminated in its surge impedence (ie 75 ohms). There are some variations on this statement but I wont go deeper.

- The wire coming out the back of the radio is probably loosely referenced against its metal chassis. Unless you want to go inside the radio your only real option is to join the coax outer to the chassis near where the single wire exits, and the centre conductor to the wire itself (after cutting it short or removing/replacing it)

- The above of course gives you an unknown RX load impedence.

- The existing power twin and earth might be usable except for the possibility of induced noise. I assume you mounted a dipole at the top of it? I would guess that it would be maybe 100-200 ohms impedence but I dont know the effect of the earth wire to that. If you had nothing better to do you could always make it into a tuned feeder length or multiples of 1/2 wavelengths. Dunno if its worth the effort though. (Tuned feeder installations allow you to have any feeder impedence provided the source and load are the same impedence. Doubt its any point doing in an RX system but worth mentioning out of interest)

- If patience was in huge supply I'd try matching at the receiver input for a 75 ohm cable. I'd go inside the radio to do this.

- If the signal is still way too low it might be worthwhile buying/building a masthead preamp to go near/on the antenna. Then noise induced by the power duct and computer would then be lower. You may also want to notch other strong stations at the input of the preamp with a series of 1/4 wave stubs so the preamp doesnt overload.

Hope this helps - or at least doesnt confuse!

Cheers Bob (Sydney Australia)

>connected to outer conductor.

I believe there's a project in the ARRL Handbook which shows how to convert a Radio Shack CB whip antenna to a 2-meter 5/8-wave - it has the details for the matching coil that is required.

http://www.arrl.org/tis/info/pdf/8009022.pdf has another QST article which shows how to construct one from scratch, using a technique that doesn't require a matching coil (the matching inductor is made from a stub).

I haven't tried either of these myself.

With regard to the version you made - did you account for the loading effect of the PVC when you measured and trimmed the length of your radiator?

Hi OM,

You reject the BalUn (matching/choking) to only presume the
implication (one wire goes to ground) forces you to use it for another
reason?

Wrong implication, even if the solution works. The one side of any
dipole/loop antenna design going "straight to ground" (ground a
euphemism for Hell?) is not a loss in any sense of the design. The
receiver is sharing the same path - unless it is strictly battery
operated without a charger connection.

Your radio wants to see a signal potential applied across its input
and chassis (as you put it, which is suitable enough). With a
monopole the input is satisfied, but you need either a ground or
counterpoise connected to the chassis. With a dipole or loop, the two
returning wires meet the radio's needs at the input/chassis
connection. A ground connection or counterpoise for the dipole/loop
would be benign in the practical sense. You won't need it (unless you
have lightning phobias); and with the common specie of radio you will
have it, somewhere, anyway (it will then simply be uncontrolled and
variable).

>Perhaps the ground of the BalUn can just go to the coax sleeve?

That will work fine.

From: Ken Bessler <kg0wx@NOSPAMyahoo.com>
Message-ID: <G4mZd.10694$Fy.725@okepread04>
Source record: 80758

I was having a problem with my new LDG AT-100PRO autotuner - If I went above 50w FM on 10 meters, The tuner's CPU would "crash". Powering the tuner off and on again would usually fix it but sometimes I'd have to re-program some of the settings.

I am trying to tune a 40m dipole that has this feed arraingment:

Rig/SWR Bridge/Switch/Tuner/RG58 (25')/RG58 coil (12 turns @ 5-1/2" dia/450 ohm ladder line (50')/antenna

Thinking I had RF in the shack, I went to Radio Shack & bought $21 worth of ferrite chokes. I put a coaxial choke on the input to the tuner and another on the output. I put a snap on (square) choke on the feedline going from the rig to the swr bridge and another on the power cable to the rig.

I tried many setups including putting chokes on the tuner's power cable and ended up with the above setup working the best.

Now (finally!) to my questions:

1) How good are radio shack chokes?
2) I was only able to get 4 turns around the feedline's choke - is that enough?
3) Am I just messing too much around trying to get a 40m dipole to tune on 10m?
4) Would I do better to add a balun and run the 450 ohm ladder line direct to the tuner?

I am trying to find a suitable connector (PL-259) for 213 cable that will screw on to the connector at the base of the above aerial. Its a tri-band white stick about 2 mtrs long.

My connectors seem to screw on about 2 or 3 turns then stiffen up and won't do up fully, as if its a slightly different thread.

I do seem to recall that there are / were two threads at some time in the past, but I have only just bought the aerial and connectors, and assumed they would be the same thread.

Can anyone confirm / answer the problem ?

Thanks,

Nick

Not reject, so much as realizing that a balun is first a way to match an "balanced" to an "unbalanced" device. I was concentrating on the impedance matching aspects, which they can also be used for. Simply because I wasn't sure how I was going to grow my antenna. Cecil mentioned that a counterpoise or ground is not needed with balanced inputs, which led me back in a circle to baluns.

Really, I'm just trying to approximate a good enough "correct" way to do things.

It would seem this is another place where various holy wars have waged over the years. My survey of the literature indicates that a great many

people don't even consider a dipole of any stripe fed to an unbalance RX/TX as a "dipole."

Isn't this the notion of many of those cheapo plastic baluns one gets to feed coax to an older TV which would have accepted parallel line? Well, I suppose these are ostensibly to match impedance, but they are described as converting balanced to unbalanced connections.

I understand that ground (as a notion) is not an absolute. I have what I have. I *may* be able to convince my landlord to let me trail a wire off the balcony to the ground. We'll see.

>>Perhaps the ground of the BalUn can just go to the coax sleeve?
>
> That will work fine.
>
According to what you suggested so far, both sides of my loop can go directly to my antenna input. Ok, can do. I'll give it a try and see if things work measurably better. Of course, I'm measuring with my ears, but I am being able to pull more signal out of the air already.

More to chew on. Thanks for your time.

Well said. And most of us who get anywhere near as much rain as Richard does (in WA) unfortunately have a LOT more lightning to deal with in the summer. In that case, shield-grounding the coax of a dipole should happen as soon as the feedline is down at ground-level, and again at the station entrance/single point ground, where it should connect to a coax surge/lightning arrestor.

Indeed, matching transformers such as Industrial Communications Engineers make, insist the metal xfmr case be grounded for safe and proper operation. I ground long wires on both an I.C.E. xfmr and a current-type Balun, directly to ground rods that the equipment is mounted on. This is also the connection point for ground radials for the long wire, if used.

Best regards,

Jack Painter

> With regard to the version you made - did you account for the loading
> effect of the PVC when you measured and trimmed the length of your
> radiator?

Hi Dave, I was just about to recommend the QST article, but you beat
me. A few comments on why his antenna did not perform: As you stated,
the PVC will change the input Z of the radiator. Just about anything
that is too close to the radiator will change things.
According to EZNEC, a 5/8 radiator with 1/4 radials 5 WL above ground
is 80-j300. As such, with a single series inductor matching section,
the best 50 ohm match is 1.6:1. This could get worse or better
depending on the antenna's environment. It will also change if you
slope the radials.
There is an article in the ARRL Antenna Compendium #1 pp.101 that
deals with 5/8 antennas. It basically explains why a 5/8, depending on
the application, is NOT the best performing radiator.

Hi Jack,

In all actuality, Seattle sees the least lightning nationwide. If
you drew a line from Seattle to Miami, you would find that the
incidence of lightning grows roughly ten-fold as you progressed along
that line.

Hi OM,

That is fortunate. Try not to introduce any grounds such as you
discuss below.

>It would seem this is another place where various holy wars have waged
>over the years. My survey of the literature indicates that a great many
>people don't even consider a dipole of any stripe fed to an unbalance
>RX/TX as a "dipole."

Dipole has only one meaning of value: Two Poles. Each pole acts as
the electromotive opposite of the other. Without opposites, no
current flows (and in a sense, a monopole finds its dipolar opposite
in ground).

>Isn't this the notion of many of those cheapo plastic baluns one gets to
> feed coax to an older TV which would have accepted parallel line?
>Well, I suppose these are ostensibly to match impedance, but they are
>described as converting balanced to unbalanced connections.

BalUns are so simple that the cheap ones work quite well.

>I understand that ground (as a notion) is not an absolute. I have what
>I have. I *may* be able to convince my landlord to let me trail a wire
>off the balcony to the ground. We'll see.

Don't go there. Introduction of alternate grounds, especially if they
do not conform to code bring the almost certainty of ground loops.
You don't even want to consider the insurance risk. There is probably
no reception advantage over the already available service ground found
at the wall socket. (I am perhaps mistakenly presuming this was for a
receiver only.)

>According to what you suggested so far, both sides of my loop can go
>directly to my antenna input.

The input and chassis, per accepted terms for both.

>Ok, can do. I'll give it a try and see
>if things work measurably better.

You may find you are already at the knee of the curve of diminishing returns. What will pay off is

1. making the antenna connection as remote as possible;
2. using coax;
3. choking that connection;
4. providing for antenna tuning at the radio.

You don't want one of that type anyway.

A plug-top unit like that will have to amplify an already attenuated
signal and will just result in noise.

You need a masthead amp to boost the signal whilst it is still
pristene, then let the cable attenuate the clean and bigger signal.

On second reading of that QST article, I admit to being a bit curious.
The K4LPQ version (with a shorted inductive stub inside the radiator,
soldered to it) is clear enough. However, the W9WQ version using a
longer, open-circuited inductive stub wire isn't a straightforward
translation of this, because there's no soldered (or other DC)
connection between the radiator and anything else!

I infer that in the W9WQ version, the stub wire is performing two
functions at once - it's adding a series inductance, and it's also
coupling the RF out onto the radiator in a capacitive fashion. This
would imply that the stub needs to provide a bit more inductive
reactance than in the K4LPQ shorted-coax version, with some of this
reactance cancelling out the radiator's -j300 and the rest cancelling
out whatever amount of capacitive reactance exists between the stub
wire and the radiator.

Am I reading this right, or am I missing something?

[Regretfully it seems likely that both W9WQ and K4LPQ are now silent
keys, so I can't ask for advice from the horses' mouths.]

>slope the radials.

I've seen a number of 5/8-wave antenna designs which deal with this
issue by using something other than a simple series coil. The
commonest approach seems to be to use a coil which is connected in
shunt between the radiator and the ground plane, with the "hot" side
of the coax being fed to a point tapped partway up on the coil. This
approach transforms the radiator impedance down to the 50 ohms needed
to match the coax, and also provides the series inductance needed to
cancel out the reactance. It also provides DC grounding for the
radiator.

http://www.fluxfm.nl/schema/5-8%20golf%20met%20radialen.PDF is one
such design. It requires some amount of tooling (e.g. to lathe down

the plastic parts to the specified configuration) but I suspect that a version could be homebrewed up using simpler materials and methods. The photos show the way to build the tapped matching coil assembly, and could probably be adapted to other coil construction methods. I believe the ARRL Handbook article which adapts a Radio Shack CB mobile antenna uses a similar tapped coil.

Another approach might be to change the length of the radiator a bit, to change the resistive part of the feedpoint impedance from 80 ohms down closer to 50 ohms, and modify the coil to suit. I haven't run any simulations to see how much change in the radiator length would be required, and what this change would do to the antenna's gain pattern.

> There is an article in the ARRL Antenna Compendium #1 pp.101 that

I'll have to look it up if I can find a copy of that edition to see what they have to say. I agree, in some cases the horizon-directed gain of a 5/8 isn't what you want. For in-city and in-the-hills mobile use, a 1/4-wave might give more reliable performance, precisely because its RF energy is more broadly directed.

Hi Ken, I have had that problem with Auto tuners myself, and could not get a satisfactory solution. The Vendors solution is Ferrite on the coax, and make sure you have a good RF ground at the tuner.
The problem is almost certainly RF feedback getting into the tuner. Since you have elimated current on the shield of the coax by the Radio Shack cores (they should work, don't know of any recent studies of these cores on 10m) that is not the problem.
The problem may be RF potential at the tuner by direct radiation. To eliminate this you need a very good RF ground directly at the tuner. For 10M this is a very short connection to a good earth ground. A 20' long ground connection is not the answer.
You might try hooking a fan 10m dipole in parallel with the 40m dipole. This would provide a better match for the Auto Tuner. If the problem is still there, then it is direct radiation. Better RF ground, or reduce power.

>Is this what I need?

That's just the (indoor) power supply, which would send DC power up the coaxial cable to a masthead amplifier.

>Why is it different from a Booster?

"Booster" is a very general and unspecific term. It could refer to either or both of two different functions.

Function #1: signal splitting and isolation. A splitter will "divide" the incoming RF power two, three, four, or more ways, and feed the power to the desired number of TV sets. A splitter also provides impedance matching and isolation, so that connecting or disconnecting one TV set from a branch doesn't cause the picture quality to change on the other TV sets.

You need a splitter to run two or more TV sets or VCRs or DVRs properly.

Function #2: amplification. An amplifier will increase the strength of the incoming signal(s) and feed the amplified signal to its output. Amplification may be needed for any or all of several reasons:

- The incoming signal at the antenna is just too darned weak.

- You're using a splitter to divide the power several ways, and a signal which was strong enough to give good image quality on a single TV set is not strong enough when split N different ways.

- The (inevitable) electrical losses in your coaxial cables are reducing the strength of the incoming signal too much.

A simple "booster" (in consumer-marketing language) is often a combination of a 2- or 4-way splitter, and a simple amplifier. It's usually installed indoors.

In many cases, the best place to add an amplifier (if you need one at all) is up on the antenna mast, as close as is practical to the antenna (hence the name "masthead"). This location allows the amplifier to increase the power in the incoming signal *before* a bunch of the signal is lost in the coax cables. It minimizes the effect of the additional noise which any amplifier adds to the signal.

So - in cases where you really do need more signal, the best combination is often:

[1] A high-quality masthead amplifier - one which can boost the weak signals *without* being overloaded by strong signals from local

stations or non-TV transmitters.

[2] A power-supply unit (such as the one your URL points to), connected to the antenna cable near where it enters the house.

[3] A passive (non-amplified) wide-frequency-range signal splitter, which has enough ports on it to feed the TV sets and etc. you care about, but no more ports than that (unused ports on a splitter do use up some of the signal power).

If you have only a single TV set, you can get by with just [1] and [2] and don't need [3].

Hi Richard, I knew that, and meant by inference that it was admirable for someone (you) with so little lightning, to realize it is not a minor-thing for others.

I might act like my station is bulletproof (because I spent the time and money to try to make it so), but when you watch that line of a storm approaching, and lightning is striking every few seconds on a path you can see coming straight for you, the realization that one is likely to land on top of you is real, not a phobia, lol. All too often, it does strike one of the tall pines in my yard, sometimes jumping to non-conductive things like wooden fences, which it splits on its way to ground.

In Virginia Beach, we get more than half the lightning Miami gets, but slightly less than half what the 100+ area of West-Central Florida does. It serves to make summer a lot less fun for those with masts, wires and towers up in the air!

Best regards,

Jack

Kristinn:

A poorly performing vertical is usually traced to an inadequate ground system, which reduces it's efficiency. Less often, it could also be caused by an electrically shortened antenna, which can experience poor efficiency. Assuming approximately one quarter wavelength for each radial, on 40 m you would want quite a few 10 meter long radials; the plot of land needed is in the order of 310 square meters. A metal roof may or may not prove to be a useful ground reference. There are a lot of things that can go wrong.

A 5/8 wavelength vertical achieves gain by pattern enhancement at lower radiation angles and sacrificing signals at higher elevation angles. If you have poor ground (in the near field) or poor ground conductivity/dielectric constant (in the not-so-near field) you probably will not be able to realize this gain. My experience with 5/8 wave verticals on HF is that they did not work as well as anticipated. If the arrival angle of the HF signal is higher than the lobe of the vertical antenna, then 'gain' has hurt, not helped.

A properly designed 4-square vertical antenna system over a good ground radial system will perform very well on 40 meters for DX. The Hy-Gain Hytower vertical antenna with a good quality ground radial system has proven to perform reasonably well on HF.

No I didn't account for the PVC ..... but I made it longer than my design
and then trimmed past my design length and it never seemed to make a
difference. Considering my inductor was also formed around the PVC that was
probably way off too.....

I modeled the whole thing with nec first. This is what my input file looked
like:
http://mywebpages.comcast.net/ka2pbt/2M-5-8wave-dat.txt

and this is what my output looked like:
http://mywebpages.comcast.net/ka2pbt/2M-5-8wave-out.txt

Construction was a radiator 58.5 inches long fed along a 1/2" sched-40,
inductor was 19 turns around the same sched-40 2 inches long. The were 4
radials at 90 deg each 19.38"

Any comments welcome ....

Thanks,

--> de ka2pbt

Hi Ken, I have had that problem with Auto tuners myself, and could not
get a satisfactory solution. The Vendors solution is Ferrite on the
coax, and make sure you have a good RF ground at the tuner.
The problem is almost certainly RF feedback getting into the tuner.
Since you have elimated current on the shield of the coax by the Radio
Shack cores (they should work, don't know of any recent studies of
these cores on 10m) that is not the problem.
The problem may be RF potential at the tuner by direct radiation. To
eliminate this you need a very good RF ground directly at the tuner.
For 10M this is a very short connection to a good earth ground. A 20'
long ground connection is not the answer.
You might try hooking a fan 10m dipole in parallel with the 40m
dipole. This would provide a better match for the Auto Tuner. If the
problem is still there, then it is direct radiation. Better RF ground,
or reduce power.
Gary N4AST

==========
Thanks, Gary.

I messed around with different chokes on different positions
until I had eliminated 90% of the problem. One of the biggest
helps was putting both a snap on square choke *and* a coaxial
choke right at the back of the rig where the HF coax attaches.

I used 2 standards - I had my son listen on the computer with
headphones and rate the FM buzz from 1 to 100. We started
at 75 and ended up at 2. I also switched from 20m to 10m and
kept track on what power level would cause problems on trying
to tune 10m. I started with 65 watts and ended with 95 watts.

I have a Cuscraft R7000 that KB0OMQ gave (!!) me - when
I get that up, I imagine my problems will be solved, at least as
far as trying to get my 40m antenna to load on 10m

Ken and Gary;

Coax fed auto tuners have a range of about 3:1 SWR. This means that for a 50 ohm feed the greatest antenna input that it can match is 150 ohms. If you want to feed any type of antenna with a generally unknown input impedance you need to use open wire feed line. Using this feed line you can auto match a wider range of miss match 10 or 15 to 1. For matching absolutely any impedance use a manual tuner.

Is that 58.5 inch figure a typo? Your NEC model says 51 inches, and
my quickie spreadsheet calculation says 50.9 inches for a 145 MHz
center of band.

I also wonder about the coil - it calculates out to be just over 1
microHenry, or about j910 ohms at 145 MHz. That seems like quite a
bit too much, based on jgboyles's posting earlier today indicating a
feedpoint Z of about 80-j300.

The PDF to which I posted a link earlier today uses a coil of only
10.5 turns, spread out over a distance of about 2.5" on a 3/4" form.
That's about .6 uH or j550 ohms... and it's a shunt-fed design so the
actual series inductance (above the tap point) is even lower.

That's roughly true for the usual (lousy) ATUs sold by the likes of Yaesu as rig accessories. It is most definitely not true in the cases of most of the third-party "coax-fed" autotuners. My LDG AT-11MP easily matches the high VSWRs presented by my G5RV on all the HF ham bands with the exception of 30M. I forget which band it is but the feedpoint impedance at the shack end of the coax falls outside the ability of my MFJ antenna analyzer to measure it which means that the AT-11MP is successfully dealing with a VSWR in excess of 12:1. The servo-tuned ATU in my old TS-940SAT is almost as good as the LDG autotuner in this respect.

It just struck me that even the "supposedly best" verticals (5/8 wl,
using good connections to the metal roof as a counterpoise) are
consistently substantially weaker on reception on 40-10m than the
inv-V. The difference varies from zero to 7-8 S-units. I would have
expected the vertical to be better in at least a few cases - but it's
not. ....

The *best* 5/8 wave antennas would not use a roof
as the ground plane. I think this is half the problem.
You are running an elevated vertical, "ground plane",
but your radial system is not resonant. This would
greatly effect the performance of most all the various
length radiators. Then you have to consider the construction
of the roof, how well each piece is electrically connected,
etc, etc..Then you mention the poor overall ground rating
for your local in general. This all combines for a mediocre
antenna. Then on top of that, you have to consider the height
above ground in wavelengths, for each particular band, and
the efficiency for each band. Naturally, the lower bands
would see the most ground losses, from the low height.
I can see a 5/8 antenna for 10m being fairly poor, when
mounted on a untuned roof. In a case like that, you should
use an elevated antenna, with elevated radials above the roof.
Or, use a 1/2 wave which requires no radials. On the lower
bands, I think the performance is probably not so good, due
to the ground system not being near as good as you think it is.
Being elevated, it really should be resonant for each band to
be used. I can see it being a toss on 20m up, but on 40m, and
lower, the vertical should be best for dx. "over 1500 miles"
If it's not, it's not working as well as it could. MK

3746. Re: Drill vs. MagMount ??

By how much? Why?

I would assume the direct connection with the roof
metal. I tried this one time, after trashing a larson
magmount with about 84 knocks off the car...
When I converted it over to a hole mount, with the
usual NMO, there was a good bit of difference. I didn't
measure, as the mag mount was toast, but it was quite
large actually. Like maybe a change for say S9 on a
machine, to maybe 15-20 over S9. Very noticable in my
case using the larson 5/8 antenna on top of a car roof.
Was like a different antenna..
MK

3747. Re: 5/8 wave 2 meter antenna matching

Newsgroup: rec.radio.amateur.antenna

Source record: 80639

Can the 5/8 wave antenna be matched with a tuning stub such as the
J-Pole uses?...

Probably, but seems easier to to use a 5 turn coil at
the base...But I agree...A 5/8 GP is not a very good 2m
antenna. Better off building a high quality 1/4 wave GP.
Seriously... By high quality, I mean instead of 3-4 sloped
radials, use 6-8 radials, and even better , use a 2nd set
for decoupling. You can also build "sleeve" versions.
5/8's are ok on HF, where the angles are not critical, and on
10m, will usually be the best choice. But on 2m, they are usually
lame.
But, don't take my word. Build a 5/8 GP, and then build a 1/4
GP, and see which is best. I bet the 1/4 wave wins. For a
5/8 to work well on VHF/UHF, it needs to be a collinear dual
5/8 design, or at the least, use sloped 5/8 or 3/4 wave radials.
5/8's with 1/4 wave radials have pretty lousy patterns for 2m use.
MK

That's very interesting. I can't see how the mag mount could change the pattern shape any, so your experience indicates a severe loss in the coupling capacitor, maybe as high as 90% or more. That's hard to imagine, so I wonder if anyone else has had a similar experience -- or, much better yet, actual measurements.

Hi,

I'm thinkinig to make an antenna for the marine band (156mhz) and hooked to my vx-7r portable.

1. How could I make it to a reasonable carrying size (perhaps less than 12 inches)?

2. Is it possible to use the steel wire and put the heat shrink tube outside?

3. Is the wire solder to the SMA core and no ground need?

Thanks,

Muskie

Wow Bob, that was some reply. Very much appreciated.

>-... but be aware that the length of coax will
>also receive in its own right if both the radio and antenna ends arent
>terminated in its surge impedence (ie 75 ohms).

Couldn't quite understand that (word ot two missing?)

>I assume you mounted a dipole at the top
>of it?

Nope, the top end is just sitting on the floor of the loft, the
surplus coiled up. Last night I did get a reasonably clean signal from
Radio 3 in stereo so we're not looking at a need for massive gains.

>- If patience was in huge supply I'd try matching at the receiver input
>for a 75 ohm cable. I'd go inside the radio to do this.

Would this need a transformer, inductance/capacitance circuit, static
resistor, or what??

Bob, could you explain one mystery to me? A normal aerial arrangement,
whether fed by ribbon or coax, is effectively one continuous loop of
wire. DC resistance is at most a few ohms - ie pretty much a dead
short. Impedence is resistance to AC, ie the signal, but the fact that
impedence is present doesn't remove the dead short. So how come
anything gets around the loop at all?!!

Or is it that the entire loop can be seen as one side of a circuit for
which it provides a potential difference?

And another: Where does this PD occur? Across the receiving element of
the aerial, or within the element relative to earth? Does this mean an
aerial 'loop" works differently from a single long wire?

You probably see what I'm getting at.

Thanks again
Paul

Ah, yes. A "magnetic" loop antenna as opposed to an "electric" loop
antenna. Funny, but none of my seminal antenna books (Kraus, Jasik,
Terman, etc.) mentions such a beast. A visit to the above website
indicates that W2BRI is referring to an electrically small loop (he
recognizes this), which is the customary term for the type of device being
described. That an electrically small loop behaves as a magnetic current
element does not qualify the use of "magnetic" in its name, IMHO. Radio
waves are electromagnetic by nature - you don't transmit or receive
exclusively radiated electric or magnetic fields. Sincerely, and 73's

Cool radio! How do you like it? Have you used it to work any ham radio satellites, or copy any weather satellite pictures? How is for cross talk? What do you think of the HF receiver? Have you copied any weather charts off of HF with it?

Since your vx-7r is not type certified as a commercial maritime radio, you need not worry about constructing an antenna suitable for transmitting.

Almost any antenna from a paper clip to the helically loaded rubber whip that came with your vx-7r will receive just fine on the commercial maritime frequencies around 156.8 MHz. If you put the antenna that came with your radio on an antenna analyzer I suspect you would see very little difference between the 146 MHz amateur 2M FM band, going up to 156.8 MHz for the maritime band or going down to 137.5 MHz for the polar orbiting weather satellite band.

Yaesu lists marine band coverage as a feature. How bad can it be? What do you want to achieve by changing your existing rubber whip?

_/_/_/

UNMATCHED WEATHERPROOFING
The VX-7R case, keypad, speaker, and connectors are carefully sealed to protect the internal circuitry against water damage. And the optional CMP460A Speaker/Mic, like the transceiver itself, is rated for 30 minutes of submersion at a depth of up to three feet!

THE BEST VERSATILITY EVER
50/144/430 MHz: 5w Power
Utilizing a reliable FET power amplifier circuit, the VX-7R provides a full 5 Watts of power output on the 50, 144, and 430 MHz Amateur bands, with bonus coverage of the 222 MHz band at 300 mW (USA version Only) of power output. And for 6-meter AM enthusiasts, you also get 1 Watt of carrier power on the 50 MHz band! Four power levels may be selected, for optimum battery life.

Dual Receive: V-V/U-U/V-U/GEN-HAM
The VX-7R is capable of four modes of Dual Receive, including simultaneous reception on (1) two VHF frequencies; (2) two UHF frequencies; (3) one VHF and one UHF frequency; or (4) one "General Coverage" frequency and one "Ham" frequency. And when a call is received on the "Main" band, you can set up the VX-7R to reduce the audio level on the "Sub" band, if you like!

Wide Frequency Coverage
With continuous AM/FM reception coverage of 500 kHz to 999 MHz (cellular frequencies are blocked and non-restorable), the VX- 7R is ideal for monitoring HF shortwave broadcasts, the AM and FM Broadcast bands, plus a wide variety of Marine, Public Safety, and Government bands. And special memory banks for the Weather, Marine, and Shortwave bands make station selection effortless!

Hi John,

If you review your references (or perhaps others) under the heading
Radiation Resistance, you would undoubtedly encounter the small loop.
It would be used to derive the math for Rr in terms of current and
magnetics, and the device would be called a Magnetic Dipole. Then the
author would probably move on to then show that the Electric Dipole
exhibits identical derivations. Magnetic antennas have a basis in a
lot of scientific literature.

Hello, and while I'm certainly aware of the term "magnetic dipole" (a theoretically tiny magnet that can be equated to a miniature current loop), I still maintain "magnetic antenna" is misleading (I would take it to mean a mag-mount antenna) and don't remember seeing it in any textbook or any peer-reviewed paper published in a respected journal such as the IEEE Transactions on Antennas and Propagation. As to how it might be used by the ARRL (a source of a wealth of practical antenna info) or the amateur radio community at large I can't say. And yes, electrically small loops are the subject of considerable literature. Sincerely,

P.S. Are any folks out there still extolling the virtues of the Crossed-Field Antenna (CFA) other than those at antennex.com?

I've had an epiphany of sorts, and I think you may be partially to blame! Well, that and "Basic Electronics" published by the US Navy.

The reason I'm so doggedly trying to get all this is that I'm also working on getting my amateur radio license. One problem with this is that I may be conflating "best practises" I'm reading about for TX with RX purposes. This is the danger of just enough knowledge. I'm determined to learn how these devices work, and how to best use them.

However, last night I realized that I can think about a RX antenna as an HF AC current /generator/ running with a small voltage potential (i.e., ~1 uV), and that my receiver completes this AC circuit.

Then it follows that a longwire needs an RF ground (of some nature) to "complete" the circuit. Hence, the use of a counterpoise in some situations. My receiver is one part of an AC circuit that wants some kind of RF ground to see the voltage potential being generated by the antenna. Crystal radio sets seem less like magic now.

Of course, grounds for lightning, static or noise attenuation is related, but not specifically part of the antenna as an AC generator.

So, my "folded dipole" (or, likewise, any doublet) does not rely on ground to complete this AC circuit, and works relatively well as an AC generator with a small voltage potential it presents at the receiver front-end. It follows that all the ground I should need (for good operation) is a good chassis ground, even if that is only the neutral side of the wall-wart (is that where it is?). Other issues like ground loops, reduction of common-mode noise &etc. is a separate issue; these can *sometimes* be solved by different devices on the antenna system, but I see now how they could also add problems.

So, when people complain about balance/unbalanced situations, they often talk about the radiation lobes of a TX antenna being uneven in some manner they would like to minimize. Perhaps there are gain issues, as well. I have no idea how my analogy works in this regard with RX antennas (perhaps my dipole will be slightly "deaf" on a particular axis if I do not balance/tune it before plugging it into my receiver), but I can take a baby step and suggest that the various things we can put between the antenna and the receiver are often RLC circuits meant to lengthen or shorten the electrical length of the wire. The main intent is to manipulate the resonance of the antenna for whatever purpose.

I know my explanation has a certain amount of hand-waving and holes, but it is really helping me understand how the antenna fits into the receiver as a total system.

The rest of your comments make a lot more sense to me when I think of things in this manner.

Thanks to everyone in this thread for coaching me in what I hope is the right direction.

As far as I can determine, "magnetic loop" (often shortened to "magloop") is a term strictly used by amateurs. It came into popular use something like 15 or 20 years ago. The name enhances the widely held mistaken belief among amateurs that it responds only to magnetic fields. I've seen the term "magnetic probe" or "magnetic antenna" in the EMC community to describe such antennas because of their near field characteristics.

The CFA antenna has transmogrified to the EH antenna, which is still being promoted by its creators and disciples. There will always be a market for this sort of antenna, along with astrology and homeopathic remedies, among people who lack the critical skills to evaluate evidence.

I have a home brew Carolina Windom that I have pruned for 80 meters. I have compared it with a G5RV and a full size inverted V for 80 meters. I like to chase 80 meter DX and I am in Southern California. The Windom gets much better reports than the G5RV on both 80 & 40 those are the only bands I checked and I can find little difference between it and the full size inverted V. Some times the inverted V will be better by one s unit then the Windom will be but for DX the Windom always seems better and I get very good reports out of the Pacific. I think different antennas work differently at each QTH and only experimenting will reveal whats best for you.

Hi Paul

> Couldn't quite understand that (word ot two missing?)

See if I can explain better..

A coax line will radiate (if its a transmitting circuit) and receive signal (as a receiving cct) if it isnt terminated into the (same) impedence at both ends of the cable that is the same as the cable itself. In other words the shield wire isnt always an effective screen. What is also an issue is if the symmetry of the source and load isnt preserved. ie if you feed a dipole direct with coax the "balanced" aerial and "unbalanced" coax will add up to an amount of line radiation. A balun is often used to balance an unbalanced feeder. This can either be a wire wound transformer or loops of coax. Feeding a vertical 1/4 wave whip is a good example of feeding an unbalanced antenna with unbalanced cable..

You can probably imagine that this coax radiating/receiving issue is a big problem when the cable runs through a cars engine compartment.

> Would this need a transformer, inductance/capacitance circuit, static
> resistor, or what??

Well that depends on the cct inside. Being a wide band device the impedence will vary greatly and no doubt have a reactive component. I have no idea what the norm is for FM broadcast receivers, even those with 75 ohm or 300ohm connectors! I'd suspect a simple L/C matching circuit would do it but might even opt for a small toroidal balun. I'd just assume that the Z would be about 300 ohms and create a 4:1 RF transformer (thats 2:1 turns) for the 75 ohm coax. The balun will tend to resolve any reactance and balance problem as well.

My personal preference for an antenna would be a single quad loop fed over the last 1/4 wave with a piece of RG62 93 ohm coax. This will match the Z of the antenna (about 110 ohms) with the coax. I'd also coil up about 5 turns of coax into a 3" loop where it feeds the antenna. This will resolve the balanced/unbalanced line radiation problem. This is of course more a transmitter config and given that you want to use over a wide range of freqs the 1/4 matching section would be a mute point.

> Bob, could you explain one mystery to me? A normal aerial arrangement,
> whether fed by ribbon or coax, is effectively one continuous loop of
> wire. DC resistance is at most a few ohms - ie pretty much a dead
> short. Impedence is resistance to AC, ie the signal, but the fact that
> impedence is present doesn't remove the dead short. So how come
> anything gets around the loop at all?!!

You have to think of the antenna as a tuned AC circuit. In fact completely throw away any thoughts of a DC circuit havning any effect whatsoever. Same kind of logic as a power transformer not looking like a short circuit. Think of the antenna as being feed by an instantaneous voltage that takes a fixed time to get from the feedpoint to where there is a "short cicruit" in the wire. The signal from one side of the coax arrives "in phase" with the one from the other side so no current flows between them. The trick is in the length of the wire in question. For a folded dipole the impedence looks like about 300 ohms provided the antenna is tuned to resonance. If you depart from resonance the conjugate impedence (resistive plus reactive) will always rise. If you start feeding this antenna at twice the freqency for what it was designed you end up with a very high impedence (say 10K plus ohms). You are now "voltage feeding" the thing.

It can and is a little more compex than this and I am not sure I have done it justice. Try another analogy. If you are pushing a child on a swing in sync with it, the energy you put in will be effectively used. If however you push in the exact opposite sense (by timing 180 degrees out of phase) you hit what look like a short circuit. Think in terms of instantaneous voltage in different parts of the antenna that change over time.

> And another: Where does this PD occur? Across the receiving element of
> the aerial, or within the element relative to earth? Does this mean an
> aerial 'loop" works differently from a single long wire?

Really testing my basic theory here! <grin>

For most applications you would tend to think that the volts would occur at the antenna feedpoint as an AC value 180 degrees difference from one side to the other. You can draw the instantaneous current and voltage on the wire if you like (and this is handy for working out the shape of the radiated pattern) but probably isnt helpful in your case.

Also think in terms of maximum power transfer with soruce and load Z... Reactance of course complicates that and the *real* theory involves looking at capacitive and indictive reactance..

I hope this all means something to you!

Cheers Bob

Hello, Roy. The use of "magnetic probe" for a small loop(s) intended to sniff out induction (near) fields from a radiating structure seems appropriate. But using "magnetic antenna" for a small loop that is to be used as a far-field receiving antenna just doesn't make sense, IMHO. Ditto for a transmitting antenna. In the case of the receiving antenna, my hunch is that all this came about because the plane of the loop when aligned with the H-field vector of an incident plane wave produces maximum current in the loop. Actually, the 51 you're seeing in the NEC model is probably the number of segments. One end is at 0,0,36 and the other is at 0,0,94.5; so yes it's really 58.5 inches. I came to this number by playing with the model until the REAL component of the impedance got as close to 50 as I could get it.

> I also wonder about the coil - it calculates out to be just over 1
> microHenry, or about j910 ohms at 145 MHz. That seems like quite a

My model comes up with a feedpoint impedance of 5.4485E+01-j2.8560E+03

So I tried to build a coil with an inductive reactance to cancel that .. I came up with 3.13 microhenries.

Is my model way off?????

The "correct" conclusion is the one that works for the individual proposing
the query.

I replaced a conventional 66' doublet with a Carolina Windom 40 LP. It was
put up in exactly the same place the doublet was. I immediately noticed that
I worked stations that I'd previously worked easier and their received sigs
were stronger as well. I also worked many stations that I'd not heard
before.

Does this mean the Windom is superior? No way! It just happened to work out
that way for my particular set of variables.

Don't forget, for every antenna you physically put up and actually yield
favorable results with, there will be a bunch of folks armed with an antenna

modeling program who will tell you why it can't work.

If it works for you, enjoy it. I'm going to try a full-wave loop next.

I can't see how the mag mount could change the
pattern shape any, so your experience indicates a severe loss in the
coupling capacitor, maybe as high as 90% or more.....

A pretty large amount...I guess it is possible maybe my
mag mount performance was down a bit due to it being
knocked off the car so many times...Not sure why that
would effect it much though..Maybe the connections were
getting a bit corroded also...Hard to say really...
Probably would be a better test to compare against a
brand new one...The one I had was the standard rectangular
looking larson mag mount. Looks sorta like a small box with
magnets underneath..I do have to say though...When I switched
to the hole mount, the increase in performance was instantly
noticable, as I knew what all the local machines did as far
as strength before the switch.
BTW, my comparison was mainly just receive on
various repeaters...Being things are reciprical, I never
really worried about transmit tests...MK

> itself. In other words the shield wire isnt always an effective screen.

This is a common misconception, but it's not true -- the presence of current on the outside of a coax line (which is the cause of radiation and signal pickup) has nothing to do with the impedance match at either end of the line.

> What is also an issue is if the symmetry of the source and load isnt
> preserved. ie if you feed a dipole direct with coax the "balanced"
> aerial and "unbalanced" coax will add up to an amount of line radiation.

That's not entirely correct, either. A coax line can be just as "balanced" as twinlead, and twinlead can be just as "unbalanced" as coax. Imbalance is caused by other factors besides physical symmetry -- see "Baluns: What They Do and How They Do It" in the ARRL Antenna Compendium, Vol. 2, for example.

I don't quite follow this, so I might be misinterpreting what was said, but it doesn't sound quite right. A small loop has a small value of resistance but a moderate amount of inductance. So the impedance (composed of the resistance and inductive reactance), although low, is considerably higher than just the low-frequency value. Although the reactance provides the lion's share of the impedance, even the resistance is quite a bit higher than the low frequency value due to skin effect. As the antenna gets larger, the inductance increases and, due to capacitive effects, the antenna eventually becomes resonant. That's the frequency at which the inductive and capacitive reactances just cancel. A short dipole antenna, on the other hand, has a much lower

impedance at RF than its low frequency value, primarily due to the capacitance between the two conductors. Its impedance is composed of a small resistance and a large capacitive reactance.

The current on the center conductor of the coax isn't in phase with the current on the shield -- it's exactly out of phase with the current on the inside of the shield. So the same amount of current that flows out of the inner conductor flows back along the inside of the shield. In this way, an antenna behaves just like any other electric circuit.

I took a look at the Smith Chart, and for impedances in this region
of the chart, series L and parallel C is not the way to get a match. In
my version, 80-j300, you need 4.7pf shunt C and .15uH series L. I have
no idea how Fig. 1C in the article managed to get a good match with the
single insulated wire up the middle of the radiator.
I seem to recall a tri-band beam (TA-33 jr.?) that used this type of
matching. Must work, so I guess I am missing something.

Yes, A 5/8 radiator with an input Z of 80-j300 with series 19cm of 450 ohm line will be about 55-j0 ohms. Of course all of this is highly dependent on the antenna environment on 2m.

It's possible he isn't creating a full match (with an L network) in this case. He might just be cancelling out the negative reactance, using a combination of (series L from the stub, and a bit of series C from the capacitive coupling between stub-feed and radiator), and not bothering with a shunt component at all. This would, perhaps, result in an 80+0j feedpoint impedance and about a 1.6 SWR at the feedpoint, which would probably end up significantly lower at the other end of the feedline due to feedline losses.

Or, there might be something stranger going on, with the stub giving a bit of shunt C to ground (in the PL-259), some parallel L/C inside the radiator, and six other bits of odd voodoo.

The author says that it ought to be possible to get down to below 1.5:1 on the repeater portion of the band... this suggests that the design isn't one which "tries" to achieve a true 1:1 match. The WA-2 and similar 5/8-wave antennas using a tapped coil seem to be able to get down arbitrarily close to 1:1 at their best.

Beats me. Almost makes me want to try building one just to measure it out and see how well it can work. On the other hand, given the comments by Cebik and others about the somewhat illusory nature of the gain advantage of a 5/8-wave, I may just stick with J-poles and quarterwave ground planes.

Quite so.

> It follows that all the ground I should need (for good
>operation) is a good chassis ground, even if that is only the neutral
>side of the wall-wart (is that where it is?).

Well, this is getting close to the mystery of your understanding. As
simple as ground is, it is so often taken for granted that many don't
really understand it at all.

As for the Neutral connection of the mains NO THAT IS NOT GROUND!

DO NOT PROCEED FURTHER with any wire work at that service until you
research this completely.

However, as a point of intuition, ground is so tightly coupled to this
wire (at RF) so as to be the missing half of the longwire system.
This is why I commented on the distinction of being completely battery
operated (hence no ground coupling).

>Other issues like ground
>loops, reduction of common-mode noise &etc. is a separate issue; these
>can *sometimes* be solved by different devices on the antenna system,

>but I see now how they could also add problems.

This goes again to the common misunderstanding. You won't suffer a ground loop until it occurs. Solving it will be one of life's greatest struggles, and the solution, if stumbled upon, will appear to be one of life's greatest mysteries. Again, battery operation creates its own bubble of isolation from these issues - however, adding a charger brings the prospects back into the equation.

>So, when people complain about balance/unbalanced situations, ...

Here you get into uncharted waters. Spend some more time here before you solo again.

The mag mount depends on capacitve coupling to ground while the "drill a whole in the roof" mount is directly connected to the ground plane.

Also, when using a hole in the roof antenna there is no problem withcoaxing being crimped in a door or window, etc. I have used the NMO (Motorola style) in the roof mounts for 2 meters and 450 MHz since 1978 with various vehicles. No problems. IMHO, it is the ONLY way to go.

All you say is true. I'm just having trouble envisioning what it is about the mag mount's effective capacitor that could cause it to dissipate 90% of the power being fed to the antenna. That's one outrageous ESR, even more so considering the size of the effective capacitor.

I personally find a mag mount to be convenient, since I use my two meter radio only a few times a year at most, and in two different cars. I'm perfectly willing to take a little hit in performance for the convenience, but not to the tune of 10 dB or more like MK reported. And if there really is any significant performance sacrifice at all, it means that there's something I don't understand and would like to. If there's a 10+ dB difference, there's something I *really* don't understand. The fact that I get a nearly 1:1 SWR with the mag mount makes it even more puzzling -- if the capacitor had an ESR of over 300 ohms (which it would have to in order to drop the signal 10 dB), the SWR would be terrible.

But "Korbin Dallas" said: "Yes a properly installed antenna will out perform a MagMount, always has alway will." That's a very positive statement, with no room for exceptions. But so far I haven't seen any reason why it should be true except for MK's single experience that doesn't make sense unless there was some other problem, like damaged coax, with his mag mount. (I can see the possibility for poor performance in an HF mag mount -- but like the OP, I'm talking only about VHF/UHF ones.)

I've used a VHF mag mount for over 20 years and have had to replace the coax only once. But then again, I use it very infrequently.

That last post got away from me too soon. Yes, I'd like a "TOA" of 9
degrees. Unfortunately, I don't have room for a 110' tower. Now what
do I do?

The gentleman has his patent.
If I disclosed how this could be beat on this forum would I still be able to get a patent for myself if I so desire? Or would it be best to not disclose it at all?
I could not see or define the advantages from what I read which is why I placed the posting.
Absolutely nothing wrong with that Roy, you must be losing it.
Actually I have heard the same thing said of your computor program instructions

Yes. It may have been nothing to do with your antennas. By chance it could have been a different time of day. Plus a different set of distant amateur stations, in different locations, at different distances, using different power and antennas, which you can't rustle up to order. As the days and weeks go by ionospheric conditions change.

Reg.

Ok,

I have not followed all of this thread.

One of the pdf's shows a shunt tapped inductor
as the base loading.

This is an auto-transformer match.

The entire inductor is set to cancel the capacitive reactance
of the aerial, then the coax feed is tapped to the 50R point,
The result is 50R J0.

For 5/8 aerials you may want to look at a physical short radiator
with a capacity hat to lower the angle of radiation.

Yes Bob, what you're saying does make some sense and will make even more after I've read it a few times. So does Roy's.

I've got a pretty good handle on the basics, having a physics degree and a long interest in hobby electronics. But as black arts go, the workings of antennae and tuned circuits come pretty high on the list!

Some experimentation is obviously needed. I'll start with a simple dipole and a run of coax, the outer screen attached to chassis. How does that sound? Is it worth buying a proper aerial or, being in the loft, would a home-made rig suffice? What would you suggest design-wise?

Money isn't really an issue - just that there's no point in buying kit that turns out to be unnecessary. As I said, the signal is already improved by hooking up the flying aerial lead to the wire in the duct.

Meanwhile I'll let you guys fight out the theory!

Many thanks for your advice

Paul

Absolutely Reg, however, to be fair to the Windom, I have had them both up
for extended periods of time with the same results. Personally, I really
don't attribute the difference to the time of day or condx in this case.
More like orientation.

It's a fact that most of the things that we take for granted where we work, like vacations, sick pay, overtime pay, the 40 hour week, retirement programs, and much else came into being because of unions. Somehow wanting a pay level and benefits that allow a decent standard of living has morphed into a bad thing. It's not unions that are the problem, it's wall street that forces management to live for the next quarter and expects un-reasonable results that is the problem. Innless of course you want our workers to live like they do in Mexico or China.

> of a 5/8-wave, I may just stick with J-poles and quarterwave
> ground planes.

Just to note that for AM broadcast verticals, the FCC requires a certain antenna "efficiency" for various classes of stations, in terms of the minimum ground wave field strength produced per kilowatt of input power to the radiator.

The FCC field strength minimum cannot be met by "Class A" stations (basically the 50kW-ers) using a 1/4-wave vertical radiator. At least a 1/2-wave radiator is needed in most cases.

The most common radiator height for Class A non-directional AM broadcast stations operating at 50kW day and night is 195ï¿½. A radiator height of 225ï¿½ (5/8 wave) maximizes ground wave field strength at a given power, but also produces a high-angle lobe that can interfere with the ground wave during night-time operation -- so rarely is used by AM broadcast stations. The ground wave field strength difference between 195ï¿½ and 225ï¿½ radiators is fairly small.

RF

Paul Davies has bad FM reception in his kitchen and would like to try an external antenna. Problem is that transmission lines require 2 wires or else they become part of the antenna themselves. The FM set has only a lone antenna wire and no ground connection.

Note that many FM sets have no antenna wire but use a clamp on the power cord to capacitively couple signal from the powerline.

Since Paul has an antenna wire, he can use the same sort of capacitive connection but to connect with the chassis (ground) that many other sets use for the "signal" connection to the set.

The clamp Paul adds around his power cord near the set chassis should connect to the inside of his coax cable shield, directly or indirectly. The antenna wire of his set can be shortened to insignificance and connected to the inner conductor of his coax.

In the loft, Paul can make a ground plane antenna to connect with his coax to the radio. The wavelength is 3 meters or about 10 feet. He could spread1/4-wave radials in a balanced and symmetrical manner to construct the horizontal part of his antenna. This would screen the vertical part of his antenna from interference and provide a terminal for the ground plane`s circulating capacitive current. Paul`s coax shield would connect with all the radial wires (2, 4, 6, or 8). Odd numbers work too so long as symmetry is preserved.

The vertical part of his antenna is a 2.5 ft. length of wire above the center of the ground plane. The center conductor of his coax connects to the vertical wire.

Paul could wind a half dozen turns in his coax directly beneath his ground plane to discourage signal on the outside of the coax. A W2DU ferrite choke could also be used. Chokes at both ends of the coax might be better. But operation may be entirely satisfactory with no chokes at all. It depends on local conditions.

Paul would have connections at both ends of his coax so it could operate as a proper transmission line,

Best regards, Richard Harrison, KB5WZI

Absolutely. I actually have home wiring experience (I don't have my
electrician's ticket, but I could wire my own home, and it would pass
inspection.) I'm surmising that the ground my receiver is seeing (at
least the DC components within it) is the neutral wire. My comment was
more of a rhetorical comment, not a threat to use the white wire on my
AC outlet as ground!

Fair enough.

I get a bit of a boost in signal running off the wall-wart, but it is
actually more convenient for me to run off batteries. I end up moving
the receiver around quite a bit. I can pick the big blowtorches and the
relays from Sackville quite nicely off the whip, so I often listen to
them in the kitchen or when doing chores around the house. For "DXing"
I settle in near the door where I've got my antenna experiments going.

This month I'm going to rig up that big loop and see how things change
from the random wire.

I have an 88 ft doublet of 26 ga. wire and 300 ohm twinlead approx 25
ft up. My MFJ-971 tuner lets me tune to SWR=1.0 at every ham
frequency from 80M to 10M. 160M not so good.

Some of the minima are very sharp and easily missed, especially on
60M. I know it is working because I am copied 60M NVIS phone 300
miles away using my 5-watt FT-817 with DYC-817 compressor.

I am no lawyer, but from what I have always heard, if you express a
general idea, that isn't a problem. However, if you are specific, or
offer enough information that someone else can reproduce your idea,
you could lose it.

i.e. 'Modifying the antenna so the angle of radiation shifts several
degrees will improve it considerably' wouldn't hurt your patent idea,
but 'Add a coil at the end with three cw turns overlapping twelve ccw
turns to improve the gain' could jeopardize your patent, or at lease
risk someone racing you to the patent office with an application.

Hi OM, it's clear you understand that wal-warts have only two connectors to AC (hot and neutral), and neutral is bonded to ground at the mains.

My question to Richard (and group) is whether there is any RF or DC link to ground via a radio's DC-power connection to a wal-wart? I have never examined the internal components of a sealed wal-wart, only seen the results of surge voltages from lightning that exploded them and damaged radios they were connected to. Nothwithstanding the forces of lightning that made that connection, isn't there isolation from ground when a DC converter is used?

Cheap DC converters can add noise to an electrical system and affect radio reception, but I didn't think there was any DC coulping across the transformer wiring, and probably limited if any rf-coupling there either. Can anyone comment on this?

It's my understanding that ground loops are most common from having serial v. parallel connections to ground from various equipments. Daisy-chaining a series of radios to the common ground would thus allow radios to exhibit feedback through each other instead of only to ground. When a properly bonded system is connected (each unit indivdually connected to the single point ground) there is no ground loop. Others often ask what about multiple bonding-points of the external ground system and it's connection to the AC mains? Answer: These are not ground loops and are not the cause of equipment interference from the series-connections of equipments described above.

That's interesting OM, as it implies you are seeing a counterpoise effect of rf-coupling across the windings of the dc transformer, or perhaps just the secondary side? If a wal-wart helps complete an antenna, it would seem there may be a design component missing from the antenna somewhere ;-)

Best regards,

From the title: "Two-Element Driven Array *With Improved Tuning and
Matching* (emphasis added)"

The major claim is that the antenna is more easily adjusted than the
alternatives. This would seem to make it "desirable."

>Efficiency would
>be reflected by the loads
>used which is not necessarily "state of the art".

What "loads"?

>He then states "a large
>F/B is effected"
> but it doesn't show before and after overlaid plots !

He doesn't claim "improved" F/B, only "comparable to that which is
available from a three element Yagi of similar electromagnetic
properties."

So what before and after do you expect to see?

>Would hams have an interest in a two element 20 M
>antenna that have lower TOA than the norm, say 9 degrees instead of the
>normal 14 degrees?

Yeah, I'm still interested in seeing how you can lower the "TOA"
without changing the antenna height, or is that the "secret"?

Egads, you blokes are helpful.

So let me get this right. I am trying to picture Richard's 1/4 wave radial arrangement. I visualise an upturned umbrella. The spokes are each 2.5ft long, joined at the middle to the coax shield. The umbella's handle is also 2.5ft long, connected to the coax inner.

(Does it matter that the local transmitters, so I gather, use horizontal polarization?)

At the other end the inner is conected to the stub of aerial wire, the shield to a clamp around the mains cable.

Does the umbrella analogy work for you?

Questions:
How big would the clamp be?
Why not connect shield to chassis?

Not quite clear on two other things, Richard
> the inside of his coax cable shield,
Contradiction in terms?

> but to connect with the chassis (ground) that many other sets
>use for the "signal" connection to the set.
Why should anyone want to connect the signal to ground?

Thanks again
Paul

I realized that my nomenclature was wrong. I should have said "bit of a boost in amplitude" because this is what I'm /really/ hearing. I'm guessing here that when running of the wall-wart we just have more available current to draw on for RF and AF amplification, heterodyning &etc. I have no proof that the signal coming into the set is any better/stronger or that my antenna is more sensitive or selective.

That is, I don't recall the signal meter changing much when I switch back and forth between battery and wall-wart. Although, quieter signals will be uniformly attenuated (along with the noise) slightly when I switch to battery.

Currently (with a random-wire antenna) the radio seems to not care what is on the "ground" side. This is hardly scientific, but when I attach a good number of feet (i.e., more than the length of the antenna) of copper wire to the ground side of the antenna input (or touch it with my hand) I get no noticeable change to tuned stations or between-station noise. I may hear the slightest bit "tick" of noise when my finger makes first contact with the case of the plug that goes to chassis ground. Nothing obvious, however.

The rules vary somewhat, it seems (I'm not a lawyer either).

Most of the world uses a "first to file" priority rule. Disclosing an invention before you file, would give someone else the ability to file for the patent first, and you'd lose.

The United States uses a "first to invent" rule, so in theory the original inventor has priority even if the invention is disclosed before filing. Winning the first-to-invent battle can be difficult, I gather... to prove priority the original inventor would need to have proof of the date of the discovery. The usual way to do that is to keep an engineering notebook, date and sign each page and have the signatures witnessed and/or notarized.

If I recall correctly, there's a limit to the amount of time that the "first to invent" rule can protect you... one year from the first public disclosure, I think.

You have up to one year to file for a U.S. patent after you publicly disclose the invention. (This isn't generally true in other countries.) I assume that Art would be aware of this since he's been through the process several times in the past. It's also easy to find at the USPTO website.

Jack,

The classic ground loop can occur even when individual components are perfectly bonded to a single point ground. The "loop" is formed when a signal cable connects the bonded components together along an alternate path. There are many proper fixes for this problem, but one popular quick and dirty fix is to disconnect the bonding by removing the third pin on the power plugs. Not a good idea, but it happens a lot.

If correcting ground loops was simply a matter of properly bonding the components to a single point then nobody would ever bother mentioning ground loops.

that's normal - wait until you discover "the paper clip principle"...

Or, "when a paper clip attached to the back of the radio receives as much as your just erected antenna", LOL. Stranger things happen, and it helps if you record in a log what your antenna experiments have yielded. If you use the S-meter to help relate signal strength (including noise levels), remember to measure it against at least three frequencies in your intended listening range (lowest, mid-range, and highest). No antenna treats the whole hf spectrum the same and you may develop favorite arrangements for particular listening desires.

Good luck,

Hi John,

Actually the driving force of that focus is called the economic policy. In other words, for years the Republican party has been intoning its mantra that taxing dividends (Capital Gains) is a bad thing. What is left is to trade shares in the expectation of their price rise (which is the strategy you describe above). So let's put the blame where it belongs, on the Administration and the current power in the House and Senate.

You will see a ban on Gay marriage before you see movement on changing Capital Gains taxes. Talk about gutless.

Just what has been the Economic Policy for the past decade? A simple revue of the Producer Price Index (this is the equivalent of the Consumer Price Index, except for how much it costs to make something) reveals that the Republican Party in Congress has consistently overseen the highest rates of business inflation. In the last four years alone many industry's Producer Prices have doubled. A simple enumeration by Industry is quite revealing where the bleeding is found:

Oil and gas extraction, the cost had been stable for 14 years before 2000, it now is up 250% Who woulda thought an oil man could be so feeble to aid his fellow wildcatters.

Total Mining, the cost had been stable for 14 years before 2000, it now is up 196% This gives meaning to Red states where Mining dominates - what has the Red Party done to stop this massive bleeding?

Petroleum and coal products mfg, the cost had been stable for 14 years before 2000, it now is up 195%. It's like this industry is off the map in Washington. Why is going to Mars a public priority?

Primary metal mfg, the cost had seen mild fluctuations for 14 years before 2000, it now is up 20%

Fabricated metal product mfg saw a cost jump of 8.5%

Gasoline stations saw a 30% plunge.

Air transportation now sees a flattening after a 60% rise over a decade. They are significantly in the hands of a Judge at Bankruptcy court.

Over the same period for Air, Rail transportation has seen only 15% cost rise. Time for Congress to kick in another bail out for Air transportation and cut Rail subsidies.

The Postal service, serving as a common denominator, has exhibited a steady increase across 30 years for a total 430% (14% annualized).

Hospitals saw a relatively flat period during the 90s and then after 2000 costs rose 22%.

Heavy construction has shown a general rise over the decade before 2000 to then find after a spike of 10% (observe in all constructions, highways, streets, maintenance, repair, new construction, residential and non-residential).

Food mfg, the cost over the past 4 year has climbed 13%

Chemical mfg, the cost over the past 4 year has climbed 10%

Plastics and rubber products mfg, the cost over the past 4 years has climbed 10%

Across the board for those industries not noted above (only because those above showed accelerating costs for the past 4 years), industry has been in a forced march of unrelenting, growing cost to produce. The ONLY exception, also noted above, has been in Gasoline sales. It would be painfully ironic to point out that this is the economic turnaround that has been the boon of invading Iraq.

So, regardless of what has caused this steady rise, what action have you seen on the hill that suggests anything is being done about it? Taxes have been rolled back from a 70% rate to less than 28% and that was DECADES ago. The cost to produce has steamrollered right over that logic.

Passing an amendment to criminalize burning the flag might do it. Outlaw abortion? There is possibly a golden bullet there for the economy. Enforce national school laws over the objections of States' Rights (who cares about States' Rights?). Criminalizing doctors whose states allow them to practice Death with Dignity? Repeal gun laws?

Where stands:
Eliminating the deficit?
Turning around the Trade Imbalance?
Bolstering the Dollar?
Simplifying the Tax Code?
Reducing the Budget?
Reducing the size of Government?

Is there any discussion of the 1994 Contract with America?
Where stands:

A comprehensive audit of Congress for waste, fraud or abuse?
Cut the number of House committees, and cut committee staff?
Require committee meetings to be open to the public?
A guarantee for an honest accounting of our Federal Budget by implementing zero base-line budgeting?
All of these cherished goals have been lost in the rush of politicians to stuff their pockets with money. Talk about gutless losers.

What significant packages are being hefted onto the table? Cut Medicare is being muttered. That will fix Hospital costs. What about fixing the $Trillion loss of Social Security? Easy, spend $Trillion for a new system, and -um- another $Trillion to keep the old system going. The new system will bring the boon of half the benefits (a new form of math that revealed in the numbers above used to be called cost inflation). What pathetic, gutless, losers.

Hi Jack,

The simple boding of neutral to ground, as you offered elsewhere,
suits the RF ground path. If there's an isolation transformer, such
as may be found in the common wall wart, you may be assured that the
interwinding capacitance is suitably high enough to overcome any
notion of being isolated at RF. Precision and low noise applications
that demand higher quality isolation between primary and secondary
mandate a faraday shield between them. This shield only insures an RF
path to ground that is optimized for tight coupling - it has no other
purpose.

Good points Gene, and thanks for your reply. The AC connections could certainly be responsible for a ground loop. But it has been my experience that so few stations actually bond properly that the preponderance of possibilities would occur foremost with the direct connection from improper bonding, not the indirect connection from electrical wiring, which usually has distance and other connections before circling back to the offending/receiving equipment. All things need to be considered, and is a good reason for Richard's comment that "Solving it will be one of life's greatest struggles, and the solution, if stumbled upon, will appear to be one of life's greatest mysteries." ;-)

I once had a ground loop from a yagi-rotor that resisted all manners of alternative grounding, wiring, routing, rf-chokes, etc. You either put up with it or remove it in that case!

If removing the third plug from the power cord isolated a ground loop problem, then safer alternatives could be accomplished such as an isolated ground and separate neutral for a particular power supply, as is common in sensitive computer systems.

Best regards,

Jack

Good question. Since FM reception became popular in vehicles, broadcasters have had to add vertical transmission to their broadcasts to better serve the mobiles.

Best regards, Richard Harrison, KB5WZI

3827. " BIG BUCKS" WITH ONLY A $6.00 INVESTMENT "NO BULL"!!!!

Newsgroup: rec.radio.amateur.antenna
Date: 2005-03-16 19:56:29 UTC
From: bscruggins2000@yahoo.com

HOW TO TURN $6 INTO $6,000!!!!!! READING THIS COULD CHANGE YOUR LIFE!

I found this on a bulletin board and decided to try it. A little while back, I was browsing through newsgroups, just like you are now, and came across an article similar to this that said you could make thousands of dollars within weeks with only an initial investment of $6.00! So I thought, Yeah right, this must be a scam,but like most of us, I was curious, so I kept reading. Anyway, it said that you send $1.00 to each of the 6 names and address stated in the article. You then place your own name and address in the bottom of the list at #6, and post the article in at least 200 newsgroups. (There are thousands) No catch, that was it. So after thinking it over, and talking to a few people first, I thought about trying it. I figured: what have I got to lose except 6 stamps and $6.00, right? Then I invested the measly $6.00. Well GUESS WHAT!!... within 7 days, I started getting money in the mail! I was shocked! I figured it would end soon, but the money just kept coming in. In my first week, I made about $25.00. By the end of the second week I had made a total of over $1,000.00! In the third week I had over $10,000.00 and it`s still growing. This is now my fourth week and I have made a total of just over $42,000.00 and it`s still coming in rapidly. It`s certainly worth $6.00, and 6 stamps, I have spent more than that on the lottery!! Let me tell you how this works and most importantly, why it works....Also, make sure you print a copy of this article NOW, so you can get the information off of it as you need it. I promise you that if you follow the directions exactly, that you will start making more money than you thought possible by doing something so easy!
Suggestion: Read this entire message carefully! (Print it out or download it.) Follow the simple directions and watch the money come in! It`s easy. It`s legal. And, your investment is only $6.00 (Plus postage)

IMPORTANT: This is not a scam; it is not indecent; it is not illegal; and it is virtually no risk - it really works!!!! If all of the following instructions are followed exactly, you will receive extraordinary dividends.

PLEASE NOTE: Please follow these directions PERCISELY, and $50,000 or more can be yours in 20 to 60 days. This program remains successful because of the honesty and integrity of the participants. Please continue its success by carefully adhering to the instructions. You will now become part of the Mail Order business. In this business your product is not solid and tangible, it`s a service. You are in the business of developing Mailing Lists. Many large corporations are happy to pay big bucks for quality lists. However, the money made from the

mailing lists is secondary to the income which is made from people like you and me asking to be included in that list. Here are the 4 easy steps to success:

STEP 1: Get 6 separate pieces of paper and write the following on each piece of paper; PLEASE PUT ME ON YOUR MAILING LIST. Now get 6 US $1.00 bills and place ONE inside EACH of the 6 pieces of paper so the bill will not be seen through the envelope (to prevent thievery). Next, place one paper in each of the 6 envelopes and seal them. You should now have 6 sealed envelopes, each with a piece of paper stating the above phrase, your name and address, and a $1.00 bill. What you are doing is creating a service. THIS IS ABSOLUTELY LEGAL! You are requesting a legitimate service and you are paying for it! Like most of us I was a little skeptical and a little worried about the legal aspects of it all. So I checked it out with the U.S. Post Office (1-800-725-2161) and they confirmed that it is indeed legal! Mail the 6 envelopes to the following addresses:

Mailing Addresses

1. P. FREY, 4577 W. PONDS CIR, LITTLETON, CO 80123
2. E. DE LEON, 14014 Rosecrest, Houston,TX 77045
3. A. Lopez, 810 Ave.J, South Houston TX 77587
4. L. Pacheco, 812 Ave.J, South Houston, TX 77587
5. K. Bat, 9335 Alcona Street, Lanham, MD 20706
6. B. Scruggins, P.O. Box 845 Port Barre, LA 70577

STEP 2: Now take the #1 name off the list that you see above, move the other names up (6 becomes 5, 5 becomes 4, etc...) and add YOUR Name as number 6 on the list.

STEP 3: Change anything you need to, but try to keep this article as close to original as possible. Now, post your amended article to at least 200 newsgroups. (I think there are close to 24,000 groups) All you need is 200, but remember, the more you post, the more money you make! This is perfectly legal! If you have any doubts, refer to Title 18 Sec. 1302 & 1341 of the Postal lottery laws.
Keep a copy of these steps for yourself and, whenever you need money, you can use it again, and again.

PLEASE REMEMBER that this program remains successful because of the honesty and integrity of the participants and by their carefully adhering to the directions. Look at it this way. If you are of integrity, the program will continue and the money that so many others have received will come your way.

NOTE: You may want to retain every name and address sent to you, either on a computer or hard copy and keep the notes people send you. This VERIFIES that you are truly providing a service. (Also, it might be a good idea to wrap the $1 bill in dark paper to reduce the risk of mail theft.)
So, as each post is downloaded and the directions carefully followed,

six members will be reimbursed for their participation as a List Developer with one dollar each. Your name will move up the list geometrically so that when your name reaches the #1 position you will be receiving thousands of dollars in CASH!!! What an opportunity for only $6.00 ($1.00 for each of the first six people listed above) Send it now, add your own name to the list and you`re in business!
---DIRECTIONS ----- FOR HOW TO POST TO NEWSGROUPS---------- Step 1) You do not need to re-type this entire letter to do your own posting. Simply put your cursor at the beginning of this letter and drag your cursor to the bottom of this document, and select `copy` from the edit menu. This will copy the entire letter into the computer`s memory.

Step 2) Open a blank `notepad` file and place your cursor at the top of the blank page. From the `edit` menu select `paste`. This will paste a copy of the letter into notepad so that you can add your name to the list.
Step 3) Save your new notepad file as a .txt file. If you want to do your postings in different settings, you`ll always have this file to go back to.

Step 4) Use Netscape or Internet explorer and try searching for various newsgroups (on-line forums, message boards, chat sites, discussions.) Just example you log on any search engine like, yahoo.com,google.com, altavista.com,excite.com then you search with this subject millionaire message board? or money making message
board? or employment message board? or money making discussions? or money making forum? or business message board? etc. You will find thousand & thousand message board. Click one by one then you will find the option post a new message.
Step 5) Visit these message boards and post this article as a new message by highlighting the text of this letter and selecting paste from the edit menu. Fill in the Subject, this will be the header that everyone sees as they scroll through the list of postings in a particular group, click the post message button. You`re done with your first one! Congratulations...THAT`S IT! All you have to do is jump to different newsgroups and post away, after you get the hang of it, it will take about 30 seconds for each newsgroup!

REMEMBER, THE MORE NEWSGROUPS YOU POST IN, THE MORE MONEY YOU WILL MAKE!! BUT YOU HAVE TO POST A MINIMUM OF 200
That`s it! You will begin receiving money from around the world within days! You may eventually want to rent a P.O.Box due to the large amount of mail you will receive. If you wish to stay anonymous, you can invent a name to use, as long as the postman will deliver it.
JUST MAKE SURE ALL THE ADDRESSES ARE CORRECT.

Now the WHY part: Out of 200 postings, say I receive only 5 replies (a very low example). So then I made $5.00 with my name at #6 on the letter. Now, each of the 5 persons who just sent me $1.00 make the MINIMUM 200 postings, each with my name at #5 and only 5 persons respond to each of the original 5, that is another $25.00 for me, now

those 25 each make 200 MINIMUM posts with my name at #4 and only 5 replies each, I will bring in an additional $125.00! Now, those 125 persons turn around and post the MINIMUM 200 with my name at #3 and only receive 5 replies each, I will make an additional $626.00! OK, now here is the fun part, each of those 625 persons post a MINIMUM 200 letters with my name at #2 and they each only receive 5 replies, that just made me $3,125.00!!! Those 3,125 persons will all deliver this message to 200 newsgroups with my name at #1 and if still 5 persons per 200 newsgroups react I will receive $15,625,00! With an original investment of only $6.00! AMAZING! When your name is no longer on the list, you just take the latest posting in the newsgroups, and send out another $6.00 to names on the list, putting your name at number 6 again. And start posting again. The thing to remember is: do you realize that thousands of people all over the world are joining the internet and reading these articles everyday?, JUST LIKE YOU are now!! So, can you afford $6.00 and see if it really works?? I think so... People have said, "What if the plan is played out and no one sends you the money? So what! What are the chances of that happening when there are tons of new honest users and new honest people who are joining the internet and newsgroups everyday and are willing to give it a try? Estimates are at 20,000 to 50,000 new users, every day, with thousands of those joining the actual internet.

Remember: Play FAIRLY and HONESTLY and this will really work. Do The Math !!!!

Hi Richard

Your right of course, but I'm not sure who is leading who in this case. I
can't tell Wall Street or the administration apart. It gets me is so many
that are being or will be hurt by the current administration, are so sure it
will not happen to them that they still vote for the current administration.
I like the headline in an European paper when Bush was reelected, "How could
250000 people be so stupid" or something close to that, I ask myself the
same thing.

Richard Fry wrote:
"The most common radiator height for Class A non-directional AM
broadcast stations operating at 50kW day and night is 195-degrees."

I won`t challenge that as I have conducted no survey. WJR Detroit is shown on the broadcast allocations map book as an unlimited (day and night) 50 kilowatt Class 1 station.

Class 1 stations operate in a clear channel (this does not mean alone on the channel) with an assigned power between 10kW and 50kW

A Class 2 station operates in a clear channel with an assigned power between 250W and 50kW. They must operate so as to not cause interference to the Class 1 stations. There are 29 clear channels which permit class 2 station operation.

Class 3 stations share regional channels and operate with assigned powers between 500W and 5kW. Thyere are 41 regional channels and more than 2000 Class 3 stations. These numbers were taken before expansion of the AM broadcast band which has grown the totals.
Class 4 stations operate in assigned local channels with no more than 1kW day and 250W night assignments. There are 6 local channels with 150 or more Class 4 stations on each channel.

Primary service area is the statiob`s groundwave coverage. Secondary service is uninterfered skywave coverage. Intermittent service lies between the primary and secondary service areas.

A clear channel has one or more high-powered stations which serve wide areas. All primary service areas and a substantial portion of their secondary service areas are cleared of objectional interference.

A regional channel has stations not exceeding 5kW which have coverage contours which limit the primary service interference between these stations.

A local channel has stations not exceeding 1 kW daytime and 250 watts at night. Primary coverage is limited by interference. Assignments are made to limit interference.

Radio waves are radiated into a hemisphere as space below the antenna is hidden by the surface of the earth. This results in a formula for the field power at one mile from a perfect radiator emitting 1 kilowatt:
P = 1000 / 16266419 = 0.00006 watts/sq mtr
E = sq rt (PR)
and R=377 ohms

Volts/mtr=152 at 1 mile from a perfect infinitely short uniform hemispherical radiator.

From a 1/4-wave vertical, it`s about 195 millivolts per mtr at 1 mile.

From a 1/2-wave vertical, it`s about 236 millivolts per mtr at 1 mile.

From a 5/8-wave vertical, it`s about 267 millivolts per mtr at 1 mile.

Volts vary as the square root of the power. So, for 50 killowatts, multiply the 1 kilowatt values by 7.07.

The field strengths are the inverse distance or lossless values. Real earth has losses.

Best regards, Richard Harrison, KB5WZI

3831. Down Tilt on Slot Antenna

I found that increasing the number of segments had a significant change in the input Z. The material I read on 5/8 antennas indicated the real part of the Z was near 50 ohms. I could not get that result until I increased the number of segments. Guess it is cause 146 MHZ antennas are a good bit shorter than 3.5 MHZ antennas, and any small deviation such as lenght, or # of segments will change the end results.

Source record: 80578

A source is spread out over an entire segment. So when you change the number of segments, you change both the length and the effective position of the source. When the source is at the bottom of a quarter wavelength radiator, small changes in source position don't make much difference in the impedance seen by the source. However, when the antenna approaches a half wavelength, the source impedance changes quite dramatically with source position. Consequently, you'll see substantial changes in reported source impedance with segmentation in that case. This might or might not be the cause of what you're seeing. As an experiment, you might try moving the source up one segment and see how big a difference it makes.

Whenever the result is very sensitive to small changes in the model, you shouldn't expect a real antenna to come out exactly like the model predicts, since small differences between the model and real antenna will likewise cause significant differences.

The absolute length doesn't matter -- a 146 MHz antenna will be no more or less sensitive to the same amount of change (in terms of percentage of the antenna size or of the wavelength) than a 3.5 MHz antenna if both are proportioned the same. In fact, 146 MHz antennas are typically considerably fatter in terms of wavelength than 3.5 MHz antennas, and this makes them less sensitive to small changes.

Probably they meant 250,000,000 (our approximate national population) rather
than 250,000. They were wrong again, as usual.
Total votes cast were approx 114,000,000 Since we were split so evenly,
politically, there were only half the total that were stupid and that gets
it down to approx. 57,000,000. Unfortunately, we probably won't be able to
agree on which half was the stupid half.

"Richard Harrison" responded (in part)
>I won`t challenge that as I have conducted no survey. WJR Detroit is
>shown on the broadcast allocations map book as an unlimited (day and
>night) 50 kilowatt Class 1 station.

Your text is referenced to out-of-date versions of applicable FCC Rules. The FCC adopted the metric standard over 15 years ago, and the classification of AM broadcast stations no longer is defined as Class 1 to 4 but Classes A, B, C & D. The current versions of the applicable Rules are contained in 47CFR Part 73, and for this topic are dated October 1, 2004.

Minimum radiator heights in meters for Class A, B and C AM broadcast stations are shown in Figure 7 of 47CFR73.190. Radiator efficiency for Class A stations (other than in Alaska) must be such as to produce a ground wave of least 362 mV/m at 1km for 1kW of antenna input power. A 90ï¿½ omni radiator cannot do that.

I just purchased an Iron Horse 17m mobile vertical. Great design, I like the ferrule to position the "stinger". My problem is that I can't find the proper length for the stinger. If we ever get an amateur band at 16.5 MHz, I'm all set, but can't seem to find the 18.1 MHz length. Does anyone know what is the starting length for the stinger for 17m? The excess length does not seem to run into a cross wire as in the Hamstick, is it possible there is something missing here?

Thanks,
Bill, W4WNT

3838. Diplexer with transition frequency between 108 and 144 MHz

Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur.homebrew,rec.radio.amateur.equipment

I am going to use the same car antenna for AM/FM and 2M. This means I need a diplexer that transitions somewhere between 108 and 144 MHz. I haven't seen something like this offered commercially. Has anyone seen a product like this, or failing that, a design I could duplicate? The antenna will be a 1/4 wave on 2M, and would also be used as a (not quite ideal) AM/FM antenna.

"Radiator efficiency for Class A stations (other than in Alaska) must be such as to produce a groundwave of at least 352 mV/m at 1 km for 1kW of antenna input power. A 90-degree omni radiator cannot do that."

Most such antennas have long been in place. Surely they are grandfathered until the station is modified.

Source record: 80585

I am using a Johnson KW Matchbox antenna tuner with a 130 foot long, 30 foot high dipole fed with about 40 feet of ladder (window) line. It works well on all bands including the WARC bands *except* for 30 meters. (it doesn't make any difference if the band switch is on 20 or 40--it will not tune 30 in either case).

The question is, does anyone have any tips/suggestions/modifications to make this also operate on 30 meters?

By the way, modifying the antenna is not an option--lucky to have it up at all with city and subdivision restrictions. Maybe could add extra ladder line in the basement shack, but would have to loop it around the basement ceiling???

73,
Carter

The answer to this is a simple one. Simply make a Slim Jim antenna using 300 Ohm feeder. Design it for 145MHz and then cut a 1" strip if metal from a drinks can and wrap it around the antenna just above the coax feed point. By sliding the metal strip up or down the antenna the resonant point will move by 10 - 20MHz. I have used this design many times, you can mark the correct point for marine band and for 2M the move the metal tuning thingy depending on where you wish to Tx. The dimensions are not critical, I have built several of these antennas for use on the marine band (ie too small for use on 2m) but by sliding the tuning strip down the antenna it works great on 2m.

The antenna can be rolled up and put in your pocket when not in use and hung from a tree any other suitable support when required. OK, it's going to be bigger than 12" but so is a 1/4W antenna at this frequency.

Yes, as the wire diameter goes to zero, the current distribution approaches the same on all elements. But in some cases (where the element height is in the vicinity of a half wavelength) the wires have to get impossibly thin to achieve good f/b with equal magnitude and correctly phased base currents. I guess you could categorize needing a finite diameter wire as a "real world effect" and a zero diameter wire as "theoretically perfect". As I mentioned, it's not hard to do well at a quarter wavelength height, but much harder at heights approaching a half wavelength. For example, I took the EZNEC Cardioid.ez example file and increased the element heights to 0.4 meter (0.4 wavelength) using 25 segments/element. With wire diameter of 10^-15 mm, the front/back ratio was still 32 dB. With the original wire diameter of about 0.24 mm, the front/back was less than 15 dB. And things get worse yet as the elements get closer to a half wavelength high. But in practice, even at a quarter wavelength height, people using phased towers might encounter an unexpectedly low f/b ratio.

For anyone who's interested, I've posted the Technical Correspondence piece on my web site. You can get it at http://eznec.com/Amateur/Articles/Current_Dist.pdf.

If I remember correctly the worst point to the rear 180 degrees
was more than 40 db down. But I must point out that nobody
accepted my theoretical analysis regarding the phase/ current magnitude
theory and even tho my models show an INCREASE in lobe width because
it reflected a circle on the gain side one should certainly question what I
say.
There are many better educated people than I on this group and if not one
came forward and blest the theory then it would appear that my theory is
flawed,
my vector diagram is flawed and also my modelling is flawed. My only
disapointment was that none came forward to point out the flaw or just
assumed without mathematical reason that it must be flawed.
Yet at the same time many are anxious to find out how I managed
to lower the TOA. even in the face of presumed flawed analysis.
Weird. very weird yet again none declared it impossible
Regards
Art

Hi Antenna Masters...

I am going to use a plumber 1/2 copper tubing for a antenna on
372.5MHz.

Using 468/F, I get about 7.5 inches per leg of dipole.

How can I readjust the formula for the 1/2 inch copper?

I read someone that diameter of the tube starts playing a row in the
UHF band.

Hi Roy

Mmmmm, yet another base belief falls screaming from the sky! <grin>

It would be interesting to know how it happened (the misconception that is). The low level thinking (for me) on a transmission line is that for a pair of wires, the signal on one side is always 180 degrees out of phase with the other. Any noise induced by a magnetic field would be in the same phase hence common mode rejection means it isnt "seen" by a RX. I cant help thinking that unbalanced line is somewhat asymetrical in that the diameter of the outer conductor would *somehow* have a non trivial width when it comes to the wavelength of the frequency in use. Needless to say I havent gone to the extent of plotting magnetic lines and rereading my base theory stuff. Some things one just has to accept!

I get the *feeling* that balanced feeder is less likely to radiate than unbalanced.

Why does one use triax in some situations? (cable damage and inadvertent DC supply grounding aside)

One hopes it is a fair statement to say that any inbalance in the current on either side of the transmission line (or phase shift ne 180 deg) will result in line radiation.. (However one gets it)

I have grabbed the ARRL balun PDF from the Eznec site and will see how I go... Have to pay some bills first!

I was trying to explain why an antenna (folded dipole or qaud) isnt really a short circuit at the operating frequency, without referring to terms like Xc, Xl, and resonance. I see I failed! What I was trying to portray was that for the amount of time and distance (aka wavelength) that the electrons had to travel around the antenna any instant in time and at any specifc place would never see a short circuit. Or of you like AC is very different to DC.

What I really want to know is whether Paul's FM RX is now working!

Cheers Bob

And why would that be? Unfortunately, there's nothing that forces this to be true. There *is* something that forces it to be true *inside* a coaxial cable -- the fact that the shield confines the fields created by the wires. But then there's the outside to worry about. And there's no such restriction on a twinlead transmission line.

I won't even try to deal with votages on a transmission line, because you lose any hope of a "ground" reference when you get more than a fraction of a wavelength away from the Earth. As far as the currents go, though, there's no reason at all that the currents on the two wires of a transmission line can't have any possible amplitude and phase relationship. These are often separated into "common mode" and "differential mode" or "odd mode" and "even mode" components for analytical and mathematical convenience. But there are, at the end of the day, two different currents on the two wires. In a coaxial cable, the common and differential mode currents are actually physically separated, the the former being entirely on the outside and the latter on the inside. If you consider the sum of the current on the outside of the shield and the current on the inside of the shield to be the "shield current", you have exactly the same situtation with coax as for twinlead -- two conductors with two currents that can have any possible relationship.

> Any noise induced by a magnetic field would be in
> the same phase hence common mode rejection means it isnt "seen" by a RX.

True only if the receiver inherently has common mode rejection, which most don't. Take a look at fig. 4 in the balun article. Imagine the "output stage" being turned around so it's the input stage of a receiver. Then suppose a noise source comes along and adds 1 mA downward to both conductors of the cable, which would represent a perfectly common mode pickup. The radio connector center conductor current would increase by 1 mA -- which would be delivered directly to the the receiver. The current on the inside of the radio chassis would increase by 1 mA, and the current on the outside of the rig would increase by 2

mA (which, not coincidentally, is the total current resulting from the noise source). The receiver would have a larger input signal as a result of that noise.

> I cant help thinking that unbalanced line is somewhat asymetrical in

>
> I get the *feeling* that balanced feeder is less likely to radiate than
> unbalanced.

This becomes a factor only when the dimensions of the transmission line become a significant part of a wavelength. At that point, you have other problems maintaining transmission line operation, and up to that point, other factors are much more important.

>
> Why does one use triax in some situations? (cable damage and inadvertent
> DC supply grounding aside)

There are situations in metrology and low level signal work where noise rejection on the order of 100 dB and better is required. Those require special shielding and techniques, but only after exceptional balance has been achieved by other means. The problems most amateurs have with current imbalance is orders of magnitude greater, and adding another shield won't help.

You can put a shield around a twinlead line which will guarantee that the sum of the currents on the two twinlead conductors and the inside of the shield is zero. But there can be a separate current on the outside, just like ordinary coax, which can radiate. You don't generally cure balance problems by adding a shield.

>
> One hopes it is a fair statement to say that any inbalance in the
> current on either side of the transmission line (or phase shift ne 180
> deg) will result in line radiation.. (However one gets it)

Yes. That's absolutely correct. A line(*), either twinlead or coax, with equal magnitude and oppositely phased currents won't radiate significantly. If the currents have any other relationship, they will. The common mode current is often defined as (I1 + I2)/2, where I1 and I2 are the currents on the two conductors defined as positive in the same physical direction. The radiation will be the same as if you had two parallel conductors each carrying this amount of current, both in phase and in the same direction -- or a single conductor carrrying (I1 + I2) and no other current. If the currents are equal in magnitude and opposite in phase, the common mode current is zero and there's no radiation.

(*) The line is assumed to have spacing very small in terms of wavelength.

The problem with extremely simplistic analogies is that a thoughtful
person is bound to try and extrapolate to gain further understanding --
just as you're doing here. And the simpler the analogy, the less he can
extrapolate before the analogy falls apart. I don't think any
explanation of AC phenomena can get very far at all without at least a
rudimentary understanding of capacitance and inductance. If there is,
you'd have to be very careful in applying it.

The minimum efficiency for Class A is 362mV/m as I posted, not 352mV/m as you "quoted me" above.

As far as the 50kW / non-D / 24-hr operations are concerned, their facilities have avoided the use of 90ï¿½ radiators nearly from their start, due to the commercial/competitive need to generate a very strong groundwave while avoiding self interference to that groundwave at night from their own high-angle radiation. The advantages of using greater fractional wavelength radiators to accomplish this has long been known and confirmed by field measurements.

I'm trying to understand the shunt tapped inductor as a circuit.

How does it work??? As long as the inductor cancels out the reactance of the radiator you just need to find the 50 ohm point on the coil ... or for that matter any feedline impedance???

Pardon my lack of knowledge.

The list below illustrates my statement above. This data for most of the 50kW, 24-hr stations with the same radiation pattern day and night was taken from a secondary source linked to the FCC database, current as of October 2004 (typos, if any, excepted).

The average height of these radiators is 188.8ï¿½, not including WFAN and KDKA.

Data Format =
Freq, Call Letters, Tower Height in Degrees, Notation

Perhaps my pestering you for the "secret" to lower "TOA" without
changing the antenna height was too oblique to qualify as "declaring
it impossible."

Therefore, let me as my congressman would say (actually not *my*
congressman, he's not that bright), "I would like to revise and expand
my remarks: It's impossible."

There are several options you can take..
Install a new set of taps on the coil for 30 meters (probably the best way to go)
Add additional caps across the matching cap
Add a variable cap on the input link
Install taps on the input link
Add a variable cap across the output where the twin lead is attached
Except for the input link, lift all other cap ties to ground
And you can add another tap on the matching capacitor..on the other side of the random wire tap and use these two together for the twin lead.

Yes, and it proves your point that non-directional 50 KW broadcast stations in the U.S. use tall towers in terms of wavelength.

The r-f is precious and it makes sense to make the most of it. Thank you for the list of high-powered stations which can be heard far and wide. I still regret the end of WLW`s 500 KW days.

Best regards, Richard Harrison, KB5WZI

3869. Low Power AM Radio Broadcasting

Newsgroup: rec.radio.amateur.antenna
Date: 2005-03-17 16:24:49 UTC
From: WCRV@webtv.net
Message-ID: <10699-4239AF51-500@storefull-3317.bay.webtv.net>
Source record: 80615

The Low-Power AM station hobby has become more popular over the past 2 years.
In the U.S, it is legal to broadcast over the AM band 540kHz-1700kHz using a 3
meter antenna and a 100mW transmitter.
Until recently, building a small AM radio station was very complicated and very expensive, until now.
Using a SSTRAN AMT-3000 transmitter, which comes as a kit for under $100.00US, or a built version which comes assembled and tested for under $200.00 US, and a 3 meter, coil loaded and tunable antenna for around $225.00 US, anyone can get on the air right now!
I get questions about range: the system I am describing has had reports from 1/2 mile to over 4 miles! Range totally depends on these factors: location, scope of the land, conductivity, choice of frequency/adjacencies, and use of this antenna.
If the transmitter and antenna are installed correctly in a proper area, several miles are possible. Many people are interested in a good, solid local signal and this system does it for a fraction of the amount of money you will spend for a comparable system.
If you are interested in low power AM Broadcasting, I invite you to visit this site:
http://antenna18431.tripod.com/antenna.htm
In this site you will find information on the 3 meter antenna, pictures of it, information and pictures of the transmitter and a link to email questions, comments and inquiries to.
If you would like to be on the air, this is an excellent choice to do it well, and at a very affordable price!

Large diameter elements make the antenna resonant at a lower frequency. Shorten the elements to resonate at the desired frequency. You'll probably find that about 7.1" will work well in your case, though without some test equipment you're likely never going to notice the difference! Resonance is NOT required for proper operation as an antenna. An advantage of larger diameter elements is that the useable bandwidth increases, though again if you're using it on a single frequency with narrow bandwidth, you'll never notice the effect.

Cheers,
Tom

If it's a single element, how in the world will you ever measure it accurately enough to KNOW what the up-or-down tilt is? That is, the directionality of a simple half-wave dipole just isn't enough to matter when you get down to a couple of degrees. In freespace you MIGHT be able to measure things that closely if you were extremely careful, but over practical ground, I don't believe you have any hope.

If it's multiple vertically-stacked elements, then arrange the feed so their currents are shifted in phase a small amount from element to element. A back-of-the-envelope picture and some simple trig should tell you just how much phase shift you should have between adjacent elements.

Cheers,
Tom

Actually, it is possible to lower the takeoff angle (the elevation angle at which the pattern is maximum) without changing the antenna height. The method is to narrow the free-space elevation radiation pattern. For example, modify the EZNEC example file W8JK.ez by changing the height (Z coordinates) to 0.5 wavelength. The takeoff angle is 25 degrees. Delete one of the elements to make a dipole and note that the dipole's takeoff angle is 28 degrees. The lowering is due to the substantially greater elevation directivity of the W8JK. There aren't too many modestly sized horizontal arrays that have enough elevation directivity to make much of a difference in takeoff angle, however, so the difference is generally small at best. It's also interesting to note that the takeoff angle of this dipole over real ground is 2 degrees lower than the takeoff angle of the dipole over perfect ground.

But as we and others have pointed out before, lowering the "takeoff angle" (as the term is used by modeling programs) doesn't guarantee better DX performance, and really doesn't mean much at all. For example, the modified W8JK has a gain of 5.66 dBi at an elevation angle of 10 degrees and 0.31 dBi at 5 degrees. If we change source 2 phasing to -144 degrees for a nominally unidirectional pattern (see the recent discussion about the impact of current distribution on front/back ratio), the takeoff angle rises slightly to 26 degrees. But the gain at 10 degrees elevation is now 6.55 dBi and at 5 degrees 1.15 dBi, both greater than the W8JK with its lower takeoff angle. And at very low elevation angles, the gain of the dipole over real ground is very nearly the same as the gain of the dipole over perfect ground, despite the difference in takeoff angles. At higher angles, the dipole over perfect ground is better, despite its higher takeoff angle.

Actual gain at elevation angles of around 2 to 10 or 12 degrees is a valid and useful measure of DX performance; "takeoff angle" isn't. But based on past performance, I'm not holding my breath that we'll be seeing any actual numbers from Art about his innovations.

Thanks, but I want to thank the ARRL. I recently enquired and discovered they generously grant blanket permission for authors of articles in their publications to reproduce the articles on their own web sites. So I'll be adding more to my web site as I have time to scan them in. I hope the articles will prompt some readers to buy some of the publications to see some of the other interesting and informative things which have been and are being written. And to support the League's ability to continue publishing. Contrary to growing popular belief, only a tiny fraction of the good information that exists is on the web.

Bob bob wrote:
"The low level thinking (for me) on a transmission line is that for a pair of wires, the signal on one side is always 180 degrees out of phase with the other."

That follows for me from the action of the simplest phase inverter, the center-tapped coil. Feed one end against the center. The other end is out-of-phase.

The current in opposite wires of a transmission line is flowing in opposite directions. Hence, the wires are out of phase.

I think a parallel-wire transmission line has a self-balancing tendency.

Two parallel wires form the simplest transmission line, with the power source at one end and a load at the other.

Distributed along the wires are series resistance, series inductance, shunt capacitance, and shunt conductance.

Power travels from the source toward the load in the incident wave. Velocity of the wave and voltage to current ratio in the wires depend on construction of the line.

The destributed inductance in one parallel wire couples with its mate to form a mutual reactance. The two wires are inductively coupled. They`re also capacitively coupled.

With inductive coupling, Lenz`s law says, "the induced current is in such direction that it opposes the change that produced it". It`s reactive, pushing back at the imposed current. It flows in the opposite direction. This is evident in self induction and secondary currents. Induced current is out of phase.

With current in one wire inducing our of phase current in the opposite wire of a long transmission line of closely coupled wires, balance between the wires is enhanced.

Best regards, Richard Harrison, KB5WZI

I'd also think that physically tilting the antenna that much might not be too much of a trick, and it should give you the tilt you need. As Tom says, it must have a tremendously narrow elevation pattern if you're going to see any significant change with that small amount of tilt.

That is exactly what I pointed to in the discussion. The top half of the
forward
lobe of a directive array is of no use say for opening a band. The important
point
is the underside contour of the main lobe where there is useful gain at the
angles
that Roy stated. For instance; a 60 foot + boom yagi with a gain of around
16 dbi
will have a TOA at say 13 degrees but it is also possible to construct a
directive array
of 10 degrees TOA that has the same underside contour as the yagi design and

thus equal
in performance. The difference is that a yagi design has a fat lobe with
narrow beam width,
where asyou can construct a radiator or an array that has a larger beam
width,
but with a thinner lobe that covers the aforementioned degrees of coverage
required.
Another point of mention is that many associate low TOA with antenna height
but
without specificity with respect to feed point height or as in other cases
such as a top hat or "unused" array as with stacked antennas
For me it is a question of phase angle provided by a transmitting point
where its optimum angle is directly opposite the earths surface and
supplimented
by a secondary radiation of a similar phase, but to explain why
would be impossible with respect to this group so don't ask

One particular poster hit things right on the head when he referred to
resistive impedance
THRU OUT the length of any radiator./s, he obviously knows his stuff tho I
question
the thin wire aproach to accomplish this i.e. negate reactance

But
> based on past performance, I'm not holding my breath that we'll be seeing
> any actual numbers from Art about his innovations.

Just for me, try to hold your breath for ten minuits.
You well know that no figures are accepted by the know
alls on this group. Even observed tests undertaken are not accepted unless
the so called guru is actually present which would be impossible , since the
gurus
wish is to preserve their perceived stations and not subject to ridicule
On this actual thread I have given explanations and figures and only
ommited how I achieve it ,which I will save until I have completed pertinent
studies.
As a former engineer which apparently you say that you are one also, it is
important
to review and check your work several times to ensure that it is in
presentable state
to fellow engineers for review. One says that it is impossible, another
somehow
turns his responses to unfounded gibberish and another declares the whole
thing as hillarious and so on, such that any comment made, even when made
in approval,
is meaningless as comments made are emotional and without any technical
depth.

Hi John, Is the shunt tapped inductor you are refering to is a coil with one end connected to the 5/8 radiator, the other end to the radials, the coax shield to the radials, and the center conductor tapped up the coil from the radials? If this is the case, according to the Smith Chart, you can only get a perfect 50 ohm match if the real part of the impedance you are trying to match less than 50 ohms. Our models indicate this is not the case with a 5/8 radiator.
The shunt tapped inductor is actually a 2 element matching system, with both elements being inductors. As you stated, the inductor in series with the radiator cancels the reactance, and the tapped shunt inductor provides a 50+j0 point. Works only if the real part of the impedance is <50 ohms.

Hi Art,

Time has proven when we do ask, you can't answer - so your advice is
commendable on two counts.

>You well know that no figures are accepted by the know
>alls on this group.

You haven't offered any
1. Data;
2. Notes;
3. Models
and certainly no
4. Figures.

>Even observed tests undertaken are not accepted unless
>the so called guru is actually present which would be impossible

Then they are not "observed tests."

Hi Carter, That's a very high impedance you are trying to match on
30m. Looks like the only options you have are modifying the Matchbox
or changing the Feedline lenght. Another poster gave some good ideas
on modifying your tuner. If you don't want to modify the tuner, then
feed the 130' dipole with 11.3' of 450 ohm line and then go 50 ohm coax
to the transmitter. Don't need a tuner. Or if you could lenghten to
ladder line to 56' that would give a good 50 ohm match, no tuner
needed.
This is a guess but I think you would need to lenghten or shorten the
ladder line 8-10' to get within range of the Matchbox.

Let's suppose you have a vertical antenna with a base feedpoint impedance of, say, 75 - j300 ohms (75 ohms resistance in series with 300 ohms of capacitive reactance), typical of a thin 5/8 wave vertical. A network consisting of 1275 ohms in *parallel* with 319 ohms of capacitive reactance has the same impedance. (Note how the Xc isn't much different from the Xc of the series circuit in this case.) If we put an inductor with 319 ohms of inductive reactance in parallel with the antenna (that is, from the base feedpoint to ground), the reactance of the inductor cancels out the capacitive reactance of the antenna, and we're left with 1275 ohms of pure resistance from the antenna base to ground (that is, across the inductor).

We can use the inductor as an autotransformer. If we tap up on the inductor some fraction k of the whole way up, the impedance we'll see at that tap will be very nearly 1275 * k^2, and it'll be purely resistive (no reactance) because the impedance across the whole coil is purely resistive. For example, half way up the coil we'll see 1275 * (.5)^2 = 1275 / 4 = 319 ohms. So to get 50 ohms, we tap up sqrt(50/1275) = 20% of the way up the coil.

Roy Lewallen, W7EL

If you put a 500pF cap in a box, with a couple of SO239 connectors so that it's in series with the coax to the tuner, you'll probably be able to tune 30M.

Adjusting feedline length is another approach.

I also have a 130 foot low dipole fed with ladderline. My feedline is
47 feet, going to an mfj tuner. I can tune 30 meters easily. You might
try adjusting the length of your feedline. You're using a different
tuner, so what you do may not match what I do, but playing with the
length of your feedline may help. Then again, it may not :-(Guess
that's why they call it amateur radio...

For what it's worth department;

I use my LP version of the Johnson Matchbox in conjunction with a 40 meter Delta loop feed with ladder-line. I tune it on 30 with the tap in the 20 meter position.

I also tune this same loop on the AF MARS frequency, way up the band from the top of 75 ham band by 500 khz. It tunes it down to 3 to 1, using the 80 meter tap.

Just for info....your results may vary depending on millions of factors.

Thanks Roy!!!

Is it possible to cancel the capacitive reactance of the antenna by placing
an inductor in series with the radiator??

i.e center of coax connected to one end of a coil with the other end of the
coil connected to the radiator. Coax shield connected to ground plane
radials.

John DK2 PBT

I'm no Roy. But, I have thought about Smith Charts alot. I wonder if
you'd consider trying to identify where the antenna's input impedance must
be located so that it might be matched with a series inductor. I'd be way
out of line to assume that you want to look at a Smith Chart for knowledge
about the effectiveness of that series inductance. But, the Smith Chart
can be a real big aid in estimating 'what it takes' to match any antenna's
input impedance.

The antenna mentioned is most likely illegal. If you have a 3 meter antenna, it must be connected to the transmitter without the benefit of a transmission line and ground lead. Don't take my word for it, ask the FCC. I did. Here is my question and their reply (note the 3 meters includes antenna, connecting lead (transmission line) and ground lead):

"Question:

Concerning the 3 meters maximum length for antenna, transmission, and ground, would a capacitance hat at the top of a vertical radiator be included in the 3 meter limit?

For clarification: Suppose I put a 3 meter vertical monopole on top of an existing structure which has a metal roof. The transmitter would be located at the base of the monopole, so it would require no transmission

line. Would I be allowed to install a 3 meter diameter (or more) top hat? The top hat would be shaped like a spoked wheel and would serve the purpose of increasing the current in the monopole through capacitive coupling to the metal roof ground.

Answer:

The intent of Section 15.219 is for a maximum 3 meter wire antenna.

The total length of the antenna plus ground lead plus connecting lead must not exceed 3 meters. The rule doesn't permit a 3 meter diameter "top hat" but should be applied to the combined length of each radial. If the combined length of each radial added to the length of the antenna vertical structure added to the length of the ground wire exceeds 3 meters, it would not be permitted."

John

Actually, the problem is that people think the "other side" that disagrees with them is stupid. No, they disagree, often for very good reasons.

The people who are stupid, or at least ignorant, are the ones who think that there is no room for disagreement.

3897. Feeding Ladderline thru window

Newsgroup: rec.radio.amateur.antenna
Date: 2005-03-18 03:41:27 UTC
From: Ed <Huckleberry_REMOVE_@bigvalley.net>
Message-ID: <Xns961CC8BA26CE5spectrumhogstarbandn@207.106.92.175>
Source record: 80542

I have a vertical slide window in my ham shack. In order to feed my coax fed antenna systems through it, I have made a 3/4" thick piece of partical board, about 6" tall amd ,mounted a couple BNC feedthru adapters in it. This works quite well for coax. The window frame itself is plastic.

I would like to use a balanced tuner in my shack, about 2 feet from the window, and feed ladderline to my antenna.

Question: What is recommended to feed the ladderline through the particle board? Could I just drill and mount a couple #6 brass bolts with solder eyes on each side of the board and use it to connect ladder line, or is something else recommended? Will this have any measurable effect on efficiency?

Thanks.

Ed K7AAT

I use plexiglas instead of particle board. Banana plugs/sockets
mounted on the plexiglas work for me. As a benefit, when the
wind blows during a thunderstorm, the antenna unplugs itself.

I use a couple of big ceramic feedthrough insulators from Surplus
Sales of Nebraska. They're mounted on a board in the bottom of my
window. The slight impedance bump from the feedthrough bolts seems to
have no effect on the ladderline. The settings on the tuner were the
same before and after installing the feedthroughs.

In another recent thread some recommended using two pieces of coax to
feed ladderline through a wall or whatever.

Another idea would be two double-female so-239 feedthrough's, plugging
the ladderline into each center hole with banana plugs (banana plugs
fit the center hole in an so-239 just fine).

3900. Help ID'ing QRM

Newsgroup: rec.radio.amateur.antenna
Date: 2005-03-18 05:04:09 UTC
From: Ken Bessler <kg0wx@NOSPAMyahoo.com>
Message-ID: <djt_d.14823$Fy.7702@okepread04>
Source record: 80544
Cross-posted to: rec.radio.amateur.equipment,rec.radio.amateur.antenna

The following website has a <1M .mp3 file of some QRM
I'm getting on 160 meters. A little background is in order:

My station has my PC about 3' away from my FT-857D's.
I've eliminated all cables except video so I'm pretty sure it's
not coming from them. I've powered off my monitor and
adjusted the refresh rate to no avail. I grounded the PC's
metal case and tried it with/without the side covers. No
difference in the signal.

Tonight I looked at my CPU temp and it was a tad higher
(127 deg F) than normal so I decided to turn on a box
fan pointed at the left side of the tower case. To my shock,
the QRM faded away! I switched the fan on and off several
times to prove my theroy. Then I made the mp3 recording you
can download here:

http://members.cox.net/kg0wx/index.html

Listen closely to the sound - at 2.2 seconds into the rec-
ording, you can hear the "tick" that is me turning on the
fan to "low". Within a few seconds, the QRM is gone!

Anybody know where I should look to find this and kill
it?

> radials.
>
> de ka2pbt

Sure. In the example I gave, where the antenna has a 75 - j300 ohm feedpoint impedance, you'd just need an inductor with 300 ohms of reactance. Then you'd have a feedpoint impedance of 75 ohms resistive. Of course, this would be useful in feeding an antenna only if the resistive part of the feedpoint resistance is close to 50 ohms or some other value your system can conveniently feed. Unlike the tapped coil method, it doesn't give you any way of transforming the resistance.

If you need to match any arbitrary impedance, say 250 - j85 or something, to 50 ohms or some other impedance, you need two things you can adjust or choose, since you have two things (R and X or magnitude and phase) which you need to transform. We could get 50 ohms resistive using the tapped inductor scheme because we could choose the capacitor and the tap position. Another very common solution is an L network, which of course has two components. In theory, we can match (or transform) anything to anything with an L network of some sort. In some special cases, one of the elements of the L network is zero or infinite, such as if we're transforming 50 - j200 to 50 + j0, where all we need is a single inductor. But this isn't generally so.

A 5/8 wave radiator conveniently has a feedpoint resistance in the neighborhood of 50 ohms, so it can often be matched well enough by simply adding a series inductor as you suggest.

3905. Insulating antenna wire for safety?

Newsgroup: rec.radio.amateur.antenna
Date: 2005-03-18 14:32:44 UTC
From: tf3kx@simnet.is
Message-ID: <cc4f4620.0503180632.7408d15c@posting.google.com>
Source record: 80550

I am contemplating running a wire, a part of a 160m antenna, along the surface of my house where it may be touched by people and animals. To prevent accidental burning or shocks from RF the wire would at least need to be insulated and preferably even enclosed in a plastic conduit, or tube, with sufficient spacing from the wire to the conduit surface. This would have to be safe for all types of weather, including rainy days when moist creeps everywhere. I am currently running only 100W, but may upgrade to a KW in the next few months.

Are there any comments or advice on the safety of having an antenna wire in a reachable position and how to prevent accidents? Minimum spacing, insulating material? Would the RF result "only" in RF burns on the surface of the skin, or worse? A similar problem comes up with above-ground radials. My antenna wires will not be visible from my operating position in the shack.

To the best of my knowledge, the only thing around my house
struck by lightning is a five foot tall live oak tree. With
antennas, towers, telephone poles, birdhouses, and 40 foot
tall trees all around, why did lightning choose to hit a
five foot tall tree? Killed half of it but the other half
is surviving.

There's a DOS BASIC program on my web page that allows one
to enter frequency, dipole length, and type of ladder-line
to obtain the length of feedline that will resonate the
entire antenna system. Your 56' is pretty close to what my
BASIC program says (54' for 10.125 MHz, 130' dipole, 450 ohm
VF = 0.9). As you say, this length gives a virtually perfect
SWR of 1:1 on 30m - no matchbox required.

The DOS BASIC program can be downloaded from:

http://www.qsl.net/w5dxp/imax.exe

Someone should tell that to Kurt N. Sterba. This
month he says: "But for a half-wave or 5/8 wave
vertical you need a parallel tuned circuit at the
base if you want to feed it there with coaxial
cable."

He also says: "A reader is irate because Kurt has
stated that coaxial cable does not radiate. Actually,
Kurt is just quoting from textbooks."

He apparently forgot what he wrote previously: "The
Resonant Feedline Dipole takes advantage of the fact
that coaxial cable acts like a three conductor cable
for RF. There is the inner conductor, the inside of
the shield, and the outside of the shield. RF signals
travel down the inside of the cable with equal currents
on the inner conductor and the shield. The current on
the shield does not penetrate the shield."

"Playing" with the length of feedline may not help but
making it about 54 feet long will solve the problem. A
little cut-and-tryin' will eliminate the need for a
tuner altogether. Of course, 54 feet of window-line may
put the impedance out of bounds on some other band.

I would think that the likely suspect would be one that does
not already have a fan. I followed the signal as it went off
freq and faded. It climbed 3 kc on 40m then faded out.

Hi Ken,

I don't quite follow the implication of your statement. Do you have a
dual CPU system, where one CPU has a fan and the other not?

As it appears to be temperature based (the reason why the fan appears
to be significant) and CPU based (over clocked for its operating
temperature); I would suggest trying to cool the CPU with an aerosol
(freeze mist) or one of those cans of air for keyboard cleaning.

Not quite. If you look at the analysis I posted regarding the tap feed, you'll see that the inductive reactance required for feeding the antenna this way isn't equal to the series capacitive reactance of the antenna. They're often close (as in the example, where the feedpoint series X = -300 and the required Xl = 319 ohms), but how close they are depends on the Q (Xs/Rs) of the feedpoint Z. When you feed the antenna this way, what you have is not a series resonant circuit but a parallel resonant one, and the required inductance is different for the two. The requirement for this type of feed is not series resonance, but that the Z at the top of the coil be completely resistive, which series resonance doesn't produce. As I pointed out in my most recent posting, you can make a series resonant circuit consisting of the antenna and an inductor, and put the source in series with that. But you need a different size inductor.

Roy Lewallen, W7EL

You can use the "canned air" as a freeze mist ("spray cold"), or vice-versa, by inverting the can while you spray. They contain essentially the same stuff, the difference being that the "spray cold" contains a syphon tube to suck liquid up while the "canned air" doesn't.

Most modern PCs use a multi-stage power regulation system. The main power supply isolates and steps down the mains power to create several DC voltages (+5 and +12 in particular) which are routed to the motherboard. Then, an on-board regulator further reduces the voltage being fed to the CPU to meet the CPU's requirements.

Modern CPUs such as the Intel P4 family and the AMD Athlon consume a large amount of current (tens of amperes) at low voltage (1.2 - 1.8 volts, roughly speaking). Modern AGP graphics cards also operate on low voltages (AGP 4x is 1.5 volts, AGP 8x is 0.8 volts if I remember correctly) at high amperages.

To create such high currents at such low voltages in an efficient manner, single- or multi-phase "bucking" voltage regulators are used. These are switching regulators, which step down the main voltage (most commonly from the +12 supply) and step up the amperage. They typically operate at switching frequencies ranging from the high tens of kHz up to the low MHz range.

I suspect that the QRM you are hearing is from the fundamental or harmonic of one of these switching-regulator oscillator rates. Heating and cooling of the CPU and motherboard are probably causing the switching oscillator to drift a bit.

As to how to get rid of it... you're already on the right track, I think... shielding and filtering. Make sure that your monitor and

power (and other) cables have ferrites on them, as close as possible to the PC case. Make sure you've got a "tight" PC chassis, with metal shielding in every possible location (including screw-secured plates over any unused PCI slots, snap-in metal shields for any unused hard-drive bays, etc.). I recommend a chassis which is actually all metal, rather than one of the new lighter-weight plastic chassis with an anti-EMI coating on the inside. Don't run your PC with the side panels off - put 'em on and fasten the screws.

As for the gamer-style transparent acrylic PC chassis, forget 'em - I have serious doubts as to whether a PC build in one of these can pass the FCC Part 15 tests, let alone be RF-clean enough to use in a ham shack.

So it *must* be a bad aerial, HI. EiRP is probably lower than 1 mW.

I've already buttoned up the all metal case with grounded side covers.
I even made sure (with a DVM) they were grounded. (The ends of the
mini tower are metal with the front having a plastic facia on top of the
metal case front).

No help. The only thing that helped was taking both covers off and
blowing air through the chassis. I monitor 3 temps - CPU, Motherboard
and power supply exhaust air. Before the box fan, I was running CPU
at 129-140, Motherboard at 100-118 and power supply exhaust at
room temp +16 degrees (F).

Now I've got CPU at 113, MB at 93 and exhaust at room + 8 deg.

I was planning on buying a can of air and further investigating this but
I feel I've solved it with the box fan. The interference is gone and my

PC is cooler.

Thanks for the ideas!

Ken,
Do you mean box fan as in a small fan installed in the pc enclosure or
are you using a big ol honkin room fan directed at your enclosure? If
you are using an AMD processor they do tend to run hotter than Intel;
I installed a second fan in my enclosure and it does keep the
temperature lower. Just something you may wish to consider - takes
less space and keeps your processor happy.

73,
Howard

It's a big honkin' $5 Wal-Mart special - taller than the PC so
I mounted the tower on stands to put the MB right in the flow
of air. The CPU is a 1.4g Athlon (not over clocked).

I've played with how far the exhaust side is away from a wall
- at 12" most of the air just blew by the components and my MB
and PS temps were not very low. Placing the right side of the
case 1" from the wall created enough back pressure to drop
both another 5-10%.

For the record I have a 2 fans on the case, 1 on the CPU and
1 on the power supply. My video card is a bit low end (Nvidia
G-force Ultra 8 meg) and has no fan. I have 340 gig of space
on 3 Westerd Digital HD's that want to run hot but with this big
box fan, are nice & cool now.

I'm thinking it's the video card.....

Cecil,
I'm pretty sure that Plexiglass is a trade name for acrylic panels.
That stuff is not at all durable. On the othe hand, Lexan (trade
name) is polycarbonate, which is very durable. It is used in
bullet-resistance glass applications, and is ideal for replacing the
window panes as you suggest. That is what I'm doing in my daylight
basement shack. A couple of banana jacks make a pretty good
feed-through in my case, since part of the house overhangs the windows
down there.

By the way, The Home Depot here in Atlanta sells both kinds of panels.

>
> Roy Lewallen, W7EL

Hi Roy, I'm OK with 319+j0 half way up the coil, but at 20% of the way up I keep getting 50+j50. I did it on the Smith Chart, and on a Spice based circuit analysis program. Too old to do this stuff by hand.
That's not a real good match for 50 ohm coax. The are other taps that will provide a better match, but no where did I find 50+j0.
In an earlier post I stated that it looked like the real part of the antenna impedance needed to be less than 50 ohms to get a perfect match, using this method.
The impedance across the whole coil is not purely resistive, it is at the 50% point. Apparently I am modeling incorrectly, or missing something.

Reg once compared them and they were close enough for
government work. I assume a VF of 0.9 for 450 ohm window-
line. Reg may assume something different or allow the user
to enter the VF. In any case, it won't be exactly 54' or
56'. Some adjustment will always be necessary.

I got it from a routine I keep on my HP48GX calculator, which comes from the following series-parallel transformations:

Let:

Rs = resistance of series equivalent circuit
Xs = reactance of series equivalent circuit
Rp = resistance of parallel equivalent circuit
Xp = reactance of parallel equivalent circuit

To convert a series circuit to a parallel circuit which has an identical impedance:

Rp = (Rs^2 + Xs^2) / Rs
Xp = (Rs^2 + Xs^2) / Xs

To convert a parallel circuit to a series circuit which has an identical impedance:

Rs = (Rp * Xp^2) / (Rp^2 + Xp^2)
Xs = (Rp^2 * Xp) / (Rp^2 + Xp^2)

These aren't very difficult to derive if you're comfortable with complex arithmetic. They should be in the toolkit of everyone who works with electrical circuits.

Important things to keep in mind when using these transformations:

1. Although frequency isn't explicitly involved in the conversions, when you make an equivalent circuit from a resistor and inductor or capacitor, Xp and Xs will change with frequency. Therefore a transformed circuit will have the same impedance as the original only at one frequency. If the frequency changes, new values of resistance and capacitance or inductance have to be calculated for the equivalent circuit.

2. Because point 1, one circuit or the other will usually be better for modeling a real circuit over a range of frequencies, because the impedance of the real circuit will change with frequency more like one or the other of the two equivalent circuits.

In the example, where the feedpoint Z = 75 - j300:

Rs = 75
Xs = 300

so

Rp = (75^2 + (-300)^2) / 75 = 1275
Xp = (75^2 + (-300)^2) / (-300) = -318.75

You can check this if you'd like. You'll find that the parallel
combination of 1275 and -j318.75 ohms is 75 - j300.

Message-ID: <2%K_d.13959$hA3.6854@trnddc09>
Source record: 80476

I plan to make a 6 element Yagi for FM reception at about 100 MHz. I
would like to use 1/8 diameter mild steel wire for the parasitic elements.
I have absolutely no experience with mild steel for antennas, but thought it
would be more bird tolerant than the copper wire model I made.
I'd sure appreciate hearing from anyone who knows about mild steel for
"VHF" antennas.

In SPICE, what coefficient of coupling did you specify between the portion of coil below the tap and the portion above the tap? The autotransformer impedance relationship I gave is strictly true only for a coefficient of coupling = 1. A real inductor will be a little less, but 1 is a decent approximation for a real solenoid of typical proportions for this application.

I'm curious how you handled coupled inductors on the Smith chart -- I don't believe I've ever seen it done.

Roy

I like your method for computing the parallel equivalent of the series circuit. I wonder if this is an appropriate place to suggest that the Smith Chart can be used to quickly estimate the parallel equivalent of the series circuits.
I sometimes overlay a "reversed" Smith Chart over "regular" Smith Chart to identify the admittance parameters of the circuit.
I've been disassociated from any antenna discusions since 1969 so I may be introducing information that everyone knows and I'm being an interferance to this discussion.

My quick and dirty "overlay" of a Smith Chart indicated the parallel circuit would be 1,250ohms resistive in parallel with 300 ohms of capacitive reactance.

My new plastic sided (gamer?) 2.8 GHz PC causes not a single problem here in the shack. My older 400 MHz Celeron however totally trashes 80 meters and is only tolerable on 40 meters, everything else is fine. Go figure.

I had a similar problem with a new computer system I recently built up.
Problem was a noisy 350W Power Supply.

I replaced it and the machine now is perfectly quiet. A good solution
for a few bucks. It is very hard to shield a computer from this sort of
noise as it radiates from the leads in addition to directly from the case

Rust ... colors towers and roofs well.

Aluminum is lighter and easier to fabricate or cut. A good sized hardware
store will have 1/8" aluminum rod or tube.

Garden stores sell coils of aluminum wire thats a bit larger than 1/8th
inch, may even be close to 3/16th inch dia. I have a coil out in the garage
but given that I don't keep a very neat garage I'm just not gonna go out at
midnight to get an exact measurement.

Will rust like hell.

Aluminum close line wire is pretty cheap and fairly thick and sturdy.

Brazing rod is a bit more expensive and really sturdy unless you have
eagles perching on your antennas.

>
> I'm thinking it's the video card......

Hummmm. I was thinking the CPU fan or the controller...Most
CPU fans vary speed as per CPU temp. It sort of sounds like
the CPU is getting hot, and the MB is telling the fan to speed
up. I was thinking either the controller is causing the noise,
or the fan itself starts to make more noise at the higher speeds.
Does the MB read fan speeds? You might look to see if the fan
speeds follow the noise. I'm not sure about any AMD "throttle back"
modes when overheated, or if that could cause more noise...
I'm having trouble seeing how the video card would increase noise,
just by being hot. Seems it would have to vary clock rate,
display types, res, etc, to change noise...What I would do is
unhook the CPU fan, and use the box fan only as a temp fan.
Then run it until it gets up to that "noisy" temp, and see if
it still does it. If so, it's likely the MB itself...If not,
it was likely the fan itself. If thats the case, it's probably
an easy fix, by using a different fan. As far as the video card,
I guess thats harder to pin down...Unless you have a 2nd card
you can sub out...If I ended up suspecting the video card, I would
install a small fan on it. They make tiny ones for this purpose..
But....I'm still having a bit of trouble seeing it as the video...
I'm kinda leaning to the fan, or it's MB controller...
Wanna talk hot CPU's? I'm running a P4 "prescott" chip...*Thats*
a hot running CPU...I use a CPU fan, a fan under the hard drives,
a big 110v fan on the side of the open case, and the PS fan...

Sounds like a 737 at the gate...:(I don't run a closed case here.
My CPU gets too hot for my tastes if I do...
Mine is all open, with AC filter material as the sides...
I get lots of dust buildup due to all the fans going 24/7...
The Prescotts require the ambient temp in the case to be 38c,
or less..The prescotts do have a throttle back mode at 70-75c I
think, and I can set one myself in the BIOS at any temp...
Mine varys what it does...Gets the hottest running the flight sim...
Maybe 52-55-58c average...Depends on the room temp...Right now,
playing usenet, it's at 45.5c.."113.9f"...BTW, if it's the MB, I
guess all you can do is just add cooling so it doesn't ever run hot
enough to go into the higher speed modes. The fan on mine is a intel
fan, and it varies gradually, not in steps..If it gets hotter,
it just gets slowly faster and faster...I've never noticed any noise
from it..But your's may be different..

Stainless welding wire, comes on a 500 metre roll.
Or get a length of the 1/4 inch plumbers microbore tube also hard drawn copper wire is quite sturdy on sorter lengths.
You just anneal it and stretch till it feels springy, by clamping wire in the vice and wrapping the other end round a stick stretch to your specks by pulling on the stick.

Hi Roy, This is where I am probably missing the boat. In both models,
I used 2 separate inductors, the sum of both being the required
inductance, in this case .35uh. I assumed that the tapped coil could
be modeled this way. I see now that this is not an auto-transformer,
it is simply 2 inductors.
The Smith Chart program has a standard transformer feature, and after
you cancel out the reactance, a transformer with a ratio of 1:0.2 gives
50 ohms. The Spice program has coupled inductors, but I will have to

do a little research to see if I can apply them to this model.
Thanks for the explanation, and thanks to others who replied by email
with suggestions.
Gary N4AST

My MB is a Shuttle AN35 Ultra (about 3y old) and it does
read fan speed (5443 rpm now) but it does not adjust fan
speed afaik.

One of these days I'll get curious and pop off a case fan and
point it at various components while listening to 160m.....

Excellent article! It really did a good job of explaining why the
current path on the outside of the coax exists and causes problems.
Also an excellent description of the various types of baluns that had
this rookie puzzled.

More please!

Yes, Roy's article in the Compendium is excellent, as are all of Roy's contributions to our art. In his article he referenced my work with baluns, which appeared in QST for March 1983. This article is also available on my web page at www.w2du.com for those who don't have a copy of that issue of QST.

Thanks for the good information on steel elements for a 100MHz yagi. I think I was concerned about something that didnt exist. I thought the fact that the steel was magnetic might effect the elements. I'm comfortable with using this steel wire now. I saw the straight lengths of wire at Home Depot where they sell it for hanging Drop Ceilings. It may not be a rust problem because of the coating on the wire But, the antennas will be in the San Diego Calif. desert anyway, so rust isnt a big problem. Besides, these are gifts so the new owners cal deal with the rust if they want clean *and* cheap.

PS I'm building this (actually several) antenna for friends who live far enough away from the city that their radio reception is poor. This "building of antennas" is strictly fun and learning for me. There is no chance of my buying any commercial antenna, even if it costs me more to build one. I did build one with copper elements and it worked very well.

All true. I see my response was too encompassing. What I was trying
to refer to was Art's "magic" design.

To wit: "Would hams have an interest in a two element 20 M antenna
that have (sic) lower TOA than the norm, say 9 degrees instead of the
normal 14 degrees?"

I can't imagine anything that will make a 2 (or any other number)
element horizontal antenna of any configuration have a TOA of 9
degrees other than placing the array center at a height of ~105' above
real ground at 14 MHz.

Walt & Roy, thank you both very much for your lifetime of service to radio. Have either of you analyzed any the numerous popular Radio Works "Current Baluns"? I was advised many years ago that the current-type balun was more effective for use with a dipole, and have used Radio Work's baluns on both dipole and random wires with success. But my measure of success is not analytical, as your studies have been. Operating a center-fed dipole at it's resonant frequency, slightly below that, and significantly above it, are the specific inquiries wrt current baluns - would a voltage balun be more effective in any of those conditions? Radio Works current baluns the same kind used in your studies?

Thanks for your comments, and the great participation of all in this group.

Hi Art,

You certainly entertain some strange fantasies - however one has to
wonder why you expose them here?

It's tough enough trying to separate the wild claims you offer from
actual work performed and then to have to wade through your mauve
musings.

Glad to hear

Hi Jack,

The typical Voltage BalUn is constructed in such a way that one lead violates the isolation offered by the Current BalUn method. There are examples found for the same application of the 4:1. One is the Guanella, the other is the Ruthroff. If you examine the Ruthroff model, you will notice that one lead of the load (antenna) is connected directly to the source without a choking intervention. On the other hand, both leads are choked by the Guanella.

By common usage, the Guanella is generally described as a Current type, where as the Ruthroff is described as a Voltage type BalUn. Current or Voltage, the more important feature is in the choking.

Roy and Walter,

CHOKE BALUNS.

Keep it simple. Why make a song and dance about it?

The pair of wires wound on a choke balun behave as an inductive choke for longitudinal currents and as a transmission line for balanced currents.

The two circuits, line and choke, behave independently of each other.

The actual current on a wire, if anyone should ever wish to know, is just the arithmetical sum of the other two.

All authors omit to say that the the pair of transmission line wires need not be coaxial. They can be a balanced twin line such as a length of stranded flexible speaker cable. Or just a pair of insulated wires laid alongside each other. Or twisted.

Not only is the twin-line mechanically more convenient to construct, it has electrical advantages. Its Zo is intermediate between the high and low terminating impedances. Typically Zo is about 120 -130 ohms. The geometric mean of 50 and 300 ohms is 122 ohms. Not that this matters very much because the device is never terminated in its nominal impedances.

Twin line also has a higher velocity factor than 50-ohm coax.

The length of line wound on the choke behaves as an impedance transformer. So it seriously, but not harmfully, affects the impedance presented to the tuner. The tuner LC settings may be beneficially affected. Otherwise the transformation ratio, which heavily depends on frequency, is not of consquence.

Preferably, the length of twin-line wound on the choke should be less than 1/8th of a wavelength long at its own velocity at the highest operating frequency.

It is not too difficult to construct a choke balun which has sufficient inductive choking reactance at 1.8 MHz without the transmission line exceeding 1/8 wavelengths at 30 MHz.

Thanks Richard. I have never seen the internal construction of the Radio Works BalUn, but it is claimed to be a current-type device. It's function as a choke was the only reason for including it in the designs of my antenna systems. I see that Reg as well as yourself remind us that is indeed their primary purpose. Too bad so many may have been fooled into using voltage-type baluns when that appears to be an inappropriate choice for may applications. I was curious what applications would benefit from such a voltage-balancing device.

Dear Carter,

As the owner of a cherry Viking Kilowatt Matchbox Tuner, I would want
to avoid any modifications of the tuner itself. So, what I do is build
up a modular approach for connecting feedlines to the tuner's balanced
terminals.

I use the General Radio design banana plug adapters as the basic
building block. They are available from Radio Shack and have the
advantages of having the exact spacing to match the 450 ohm ladder
line and being both a jack and a plug at the same time as screwing
down the ladder line.

My approach is t ohave a short piece of 450 ohm ladder line from the
Tuner Terminals to a GR banana connector. The antenna feed line has a
similar GR banana connector at its end. When lighting is in the
vicinity I disconncect the connectors and throw the feedline to the
floor or to an earthing.

Whenever I need a matching network for a given antenna due to extreme
mismatches, I build that network between two GR banana connectors and
just plug it in series with the line and tuner. The network is usually
as simple as two inductors wound on PVC or it could be just a mica
transmitting cap or a vacuum cap or any combination or balanced L or
Pi circuit components.

It helps to have a means of measuring the misbehaving antenna's
impedance at the end of the feedline at the frequency in question and
then design and build the necessary matching network based on the

Smith Chart solution.

I dont know about Iceland, but in the US at 160m you are required to perform an RF safety evaluation at PEP 500+ Watts. My personal suggestion is that you have no business even thinking about going 1kw when you cant answer this question yourself. IMHO this is a really bad idea, and with all due respect, I think you need a bit more education (like learning to do the safety eveluation, which would answer your questions) before you fool around and hurt someone.

My bag is VHF, so forgive me if I've bumbled up the calculations. My numbers show that a standard 108" whip has an input impedance of somewhere around 0.04 ohms in series with a 22 pf capacitor.

These numbers are so far from what I normally deal with that I'm not sure that I'm right, and I'd appreciate somebody who actually works down in this area giving my numbers a reality check.

If they ARE right, how in heaven do most people match to 0.04 ohms? The 22 pf I can resonate out with a 1 millihenry choke (or thereabouts), but how do most people match 50 ohms to fractional ohms in the homebrew arena -- that is, without just going out and buying a "magical matching box" of some sort?

Jim

No, since I figured out what baluns do and wrote the article, I've never purchased a balun since I know how to make effective ones myself. When I wrote the article, the popular commercial baluns were all "voltage baluns", and I'd like to think that the article was a factor in causing the gradual changeover of commercial products to "current baluns".

> I was advised many years ago that the current-type balun was more

> effective in any of those conditions?

Your question indicates that my article failed to explain one of its major points. The answer is no, a voltage balun is not more effective than a current balun in any antenna/feedline application. If the antenna is perfectly balanced, the third winding in the voltage balun will carry no current and does nothing. If the antenna isn't balanced, the presence of the voltage balun's third winding will prevent balanced currents in the elements. So at best the voltage balun does as well as a current balun, and otherwise it degrades balance.

> Radio Works current baluns the same
> kind used in your studies?

Sorry, I've never purchased one and taken it apart. You might try asking them.

> Thanks for your comments, and the great participation of all in this group.
>

You're welcome. I'm surprised and frankly disappointed that so many people haven't seen the article before. It's been in print for 20 years, and frequently mentioned on this newsgroup and elsewhere. There are a lot of other good articles in the _Antenna Compendium_ series -- people who don't have a set have been missing a lot. But it seems like, more and more, that the web has become the sole source of information for a growing number of people. Make that the web, AM talk radio, and Fox news.

Roy,
Although no credit is given or author claimed, the Radio Works Product Manual includes a similar drawing and detailed explanation of same. This has been in print every year for at least the 6 years that I have been buying products from them. It is the basis for their design, production and marketing of the current-type baluns. Radio Works also recommends a line isolator at the transmitter-end, due to near field coupling of antenna currents onto the coax shield that a Balun cannot prevent. I have never used that product but it is popular.

Not quite. Over perfect ground the Z is ~ 0.37 -j8170 @ 1.9 MHz for a
12mm diameter radiator.

So you add an inductor of +j8170 with say Q=250. That gives Z =
(0.37+32.68) +j0 = 33.05 +j0. Then you add 16.95 ohm of ground loss
and Z = 50 +j0.

A perfect match with a gain of -17 dBi. :) Easy huh?

Hi Jim, Your numbers look about right for a 108" whip on 1.8mhz. To feed a small whip like this you would have to "brute force" it with a large loading coil at the base. The efficiency will be low and the bandwidth narrow. To get any efficiency at all, the 2:1 swr bandwidth will only be around 5khz. Once you tune it up, it will be a single frequency antenna.
There are things like adding capacitive loading at the top of the whip, and moving the inductive loading to the center (have to cut the whip in half). This will make the feedpoint Z a little more managable. I once loaded an 8' antenna on 160, just to see if I could, but never got on the air with it. I read somewhere that in the 50's, law enforcement 2-way radios operated close to our 160m ham band. Wonder what kind of antennas they used on the police cars. Of course the distances they were interested in are different from hams.

Roy,
Thank you for your concise description of the auto-transformer.
Now to inject a little spice into the equation;)
Perhaps you would like to tackle the auto-transformer
configured as; Ground|--\\\\\\\---50R J0(from Tx)
^------To Antenna
Thanks again,
73

Art"

End quote

Doesn't the foregoing *exact* quote say, "...two element 20 M
antenna....?"

>You mentioned horiuzontal (sic) antenna which suggests a yagi (sic) design unless you
>intended
>horizontal "polarisation".

Okay polarize it any way you want, and I don't see where I mentioned
Yagi at all.

>Roy, same as I, is pointing out the number of
>incorrect statements that you have made and you are now adding to them.

Roy made a valid point. You on the other hand are full of it.

>To help you out I will stop posting on this thread to save you any further
> embarrasment (sic), that way you will not need to admit to anymore (sic) errors.

When you can show me an error, I will admit to it. So far there's
nothing to admit to. But I can understand your desire to drop out.

>Pity you didn't define what you meant with respect to antenna height i.e.
>feed point height, top hat height, a higher unfed antenna height and so on.

I said, "array center." If you want to vertically polarize it you
might make it at ~70 to 80' with a pair of collinear dipoles if you
can figure out a practical way to feed it. That would give a whopping
4 - 5 dBi at 9 degrees, where my Yagi design at 70' has 12 dBi at 9
degrees even though the max gain is at 13 degrees. (One of the points
Roy was making)

You're claiming some magic design that will lower the "TOA"
significantly, from the "norm" (from whatever hat that came from) of
14 to 9 degrees, without increasing the antenna height. I'm
suggesting that you can't do it. Prove me wrong - wait a minute; you
already confessed that you couldn't.

>Adding ambiguety (sic) just leads to confusion for everybody.

This coming from an expert at bafflegab.

And speaking of bagglegab...

If you follow NEC guidelines on the minimum recommended segment length/wire radius ratio, you should have no more than 17 segments; the model has 127. In this case, though, it doesn't seem to be disturbing NEC-2 very much. Also, the half inch diameter is somewhat greater than most CB whips. If you drop the diameter to a quarter inch, you'll get a substantially greater reactance which would require a larger loading inductor and hence result in lower efficiency. Otherwise it looks ok to me.

As Wes pointed out, the ground system and loading inductor losses will be so large as to make the feedpoint resistance (and wire loss) insignificant. The zero-loss feedpoint resistance is, however, useful in determining efficiency. If you set the wire loss to zero by removing the LD "card", you get the more useful value of feedpoint resistance when losses are zero, 0.098 ohms. Using Wes' value of about 50 ohm feedpoint resistance when losses are included, you can calculate the efficiency as 0.098/50 = 0.2%, or 2 watts radiated for each kW applied. In American mobile terms that's 1.5 watts per horsepower. I'm always glad to see more QRP signals on the band.

To obtain obtain some idea of the numerical values involved with mobile, short, antennas on 160 meter and other low frequency bands, download programs -

HELICAL3
VERTLOAD
LOADCOIL

from website below. Takes only a few seconds to download. Not zipped up. Run immediately.

With a very short antenna, to obtain a useful efficiency, a physically large loading coil is essential. The only space available is up the antenna. So the best thing to do is extend the coil up the antenna from near the base, in the form of a long slender helical winding on a pvc plastic pipe.

The whole thing behaves as a short 1/4-wave resonant vertical. There is a short rod at the top which is pruned to resonate the antenna in the required band. It is inevitably a single frequency job. The bandwidth on 160m is only a few kHz.

With a 100 watt transmitter, when both vehicles are in the low-noise countryside, it is possible to work 100 miles or more, on groundwave, in daylight. Much further via skywave in darkness. G3YXM has worked transatlantic from a car in Scotland to a base station in Canada on occasions.

Maximum overall antenna heights are about 9 feet above roof of car with the coil about 2" in diameter, the coil extending to a height of 6 or 7 feet.

The most tedious procedure is pruning all antenas in a group of mobiles to the same frequency on the 160 meter band. But it has been done. Mobile to a base station is easy. For many years the standard UK frequency for mobiles was 1930 kHz.

Matching from antenna base to a 50-ohm transmiier can be accomplished by a single or bank of mica capacitors of several hundred pF.

For quite a number of years, mobile working on 160m was quite popular in the UK using helically-wound antennas.

Hi Frank, Well, I got different numbers than both of you. Must depend
on the ground type of the models, as well as the # of segments.
If you are trying to match an antenna with fractions of an ohm
resistive and thousands reactive, the differences we are all observing
will not make a whole lot of difference in the matching network you
decide to use. It will be big and bulky, and very inefficient.

BTW, Mr. Monser was a 1947 Connell University graduate in Electrical
Engineering.

Cornell's alumni magazine reported that: George J. Monser ('47 BS EE) of Las
Vegas, NV, formerly of Goleta, CA,
passed away on January 4, 1998. He was a retired consulting engineer for
Raytheon Corporation and author.

My bad. I hate it when that happens. A typo on the length on my
part. 101 instead of 108.

It's more like 0.12 -j2890 in EZNEC. I'm not real fluent in NEC decks
but I think you are using too many segments.

I should have read the manual before modeling, but I was so concerned that the feed-point be near the bottom. Changing the segmentation to 17, removing the LD card, and reducing the radius to 0.125 ", calculates the feed-point impedance as: 0.123 - j3286. I considered Jim's calculation of 0.37 - j8170 to be far too reactive. The fact is these points are so close, when observed on the Smith chart, as to be virtually identical.

Analyzing a shunt L/series C matching network, with inductor Q at 300, indicates a loss of 21.5dB with 30 kV RMS at the base of the antenna (1.5 kW into the matching network). (In the case of 0.37 - j8170 the loss is 21.8 dB, with 42 kV at the base). These voltages are so large, I am beginning to wonder if I goofed again! The losses, at least, are the same order of magnitude as Roy's calculation.

73,

Frank

I built a 2 meter 6 element beam out of some single strand guy wire. It
worked fine for a year or so that I had it up. There is no electrical
problem with steel but mechanical it may be something else. Rust being one
of them, the small size of the elements at 100 mhz may not be able to stand
up under wind.

ASCII art was never my forte;)

In this configuration the transmitter feeds the top of the
auto-transformer coil with the bottom of the coil at ground
and the antenna is tapped along the coil.
hope that makes more sense?

If you had made this model with EZNEC, you would have seen a warning
that the segment length is shorter than recommended. And you could have
entered the dimensions directly in inches (or immediately converted
between meters and inches). The free demo program is adequate for this
model, providing you don't want more than 20 segments.

You might consider using Copperweld wire. That way you have both the strength and the freedom from rust. It's not mild, however -- it's hard and springy, so it would be harder to work with.

Roy Lewallen, W7EL

Now I understand what you're describing. That could match an antenna having parallel transformed feedpoint R less than 50 ohms and moderate capacitive reactance. But it's probably not the best way to do it. You couldn't feed a 5/8 wave vertical this way, because the parallel transformed feedpoint R is greater than 50 ohms. The portion of L below the tap would be the value needed to resonate with the equivalent shunt Xc of the antenna. Then the additional turns would simply be the rest of the autotransformer to step up the equivalent parallel feedpoint R.

Art, please fill in the blanks. Trust me, it won't harm in any way your ability to obtain a patent.

Hi, I'm aunwin. I have invented an antenna that's an improvement over existing designs, because:

1. The gain of a __[A]__ when mounted ______ feet high is _____ dBi at an elevation angle of __[B]___ degrees. My remarkable antenna has a gain of ____ dBi at that same angle.
2. At the same frequency as used to determine the gain in item 1, the reference antenna has a front/back ratio of ______ dB at an elevation angle of __[B]__ degrees. My marvelous antenna has a front/back ratio of ______ dB at that same angle.
3. At a frequency _____% [above|below] the frequency of items 1 and 2, the reference antenna's gain has dropped to _____ dBi and the front/back to ____ dB. My terrific antenna, however, still has a gain of ______ dBi and front/back of ______ dB.
4. When matched to 50 ohms at the frequency of items 1 and 2 which is ____ MHz, the reference antenna has a 2:1 SWR bandwidth of _____ MHz. My outstanding antenna has a 2:1 SWR bandwidth of ______ MHz.

A = the name of a reference antenna having a similar size, number of elements, complexity, or cost compared to your antenna. In other words, a common antenna that your antenna is better than.
B = an elevation angle useful for DX work -- choose anything between 2 and 10 or so degrees. It would be best to give gain and front/back for multiple angles.

That'll show those ignorant troglodites like Roy and Wes that there are still Galileos out here who can laugh in the gurus' faces and come up with performance they never dreamed of! You wanted numbers, I gave you numbers. Choke on those, you doubters!

That's all you've got to do, Art, just fill in the blanks. A few numbers. No need for expositions on coupling, polygons, or takeoff angles.

Not holding my breath,

Roy Lewallen, W7EL

Hi Group,

I have a problem with my CDE AR-40 rotor controller box. The controller will drive the rotor into the limit without stopping. I can swap connections 4 and 5 and it goes into the limit in the other direction.

I brought the rotor down and checked it on the bench to verify that it was not a cable problem. I also checked it on another rotor with same.

Any one help with a schematic or has seen and fixed this problem before?

Amateur Radio Military Appreciation Day

http://www.freewebs.com/kb9ibw/

WHAT IS ARMAD ?

ARMAD is an annual Amateur Radio Special Event project that stands for Amateur Radio Military Appreciation Day. We work with National Military Appreciation Month during the month of May. Amateur Radio Operators from around the world team up during this joint effort to allow the people from our communities to gather at public locations such as shopping centers, parks, VA hospitals, and sporting events to express verbal positive support "LIVE" over the radio for members of the Military, Veterans, Reserves, National Guard, and military support groups. It is also a chance for those at each location to hear and exchange messages of appreciation with each other over the radio. Many of us have friends, relatives, and neighbors that are active duty, and past members of the armed forces. ARMAD gives us the chance to support one another, and to express our thanks and appreciation to those that sacrifice and serve in the Armed Forces.

I forgor to mention that I recently wrote an addition to Chapter 21,
Chapter 21A for Reflections 3, telling what led to the development of
the W2DU balun. It also appears on my web page under the category
"Preview Chapters from Reflections 3," The idea came while fixing a
problem that arose in measuring the radiation patterns of antennas I
developed for use on various spacecraft at the antenna lab of the RCA
Space Center, Princeton, NJ in the 1970s

> but I think you are using too many segments.

A more realistic analysis than above, with the following structure, produces
some interesting results:
9ft monopole, segmented in 12" lengths, mounted above a 6' x 6' wire grid
model, also 12" segments, (All wires # 10 AWG). 5 ft above a
Sommerfeld/Norton average ground (Er = 13, Sigma = 5 mS/m). Frequency 1.9
MHz.

Zin = 1.23 - j3059, max gain = -8.3 dBi at 25 deg. elevation. (surface
wave not computed). Structure
efficiency 98.7%.

A suitable matching network, assuming an inductor Q of 300, consists of a
shunt "L" (161uH) followed by a
series C (16.2 pF). The network loss is 11.5 dB and 28 kV RMS at the base

with 1.5 kW in.

With an inductor Q of 1000, the component values become: L = 193.5 uH, and C = 8.88 pF.
Loss = 6.3 dB, and 51 kV RMS.

Frank

Either he's wanting to verify the true omni staus of the vertical by
experimentation or (more likely) he's installed a quickie vertical in place
of a busted beam, while he rebuilds the beam. Do you know the fellow well
enough to ask, so we can know for sure which it is?

Walt
Give credit where it's due.
There is an "effect". But it doesn't widen the 2:1 SWR bandwidth.
It merely makes the negligible reflected power near resonance nearly vanish
if you get the resonance of ALL the parts perfectly equal.
An interesting academic exercise, but no magic solution.
There is no free lunch.

OTOH

I LOVE my SteppIR 4 element beam!!!

WHAT IS ARMAD ?

http://www.freewebs.com/kb9ibw/

ARMAD is an annual Amateur Radio Special Event project that stands for Amateur Radio Military Appreciation Day. We work with National Military Appreciation Month during the month of May. Amateur Radio Operators from around the world team up during this joint effort to allow the people from our communities to gather at public locations such as shopping centers, parks, VA hospitals, and sporting events to express verbal positive support "LIVE" over the radio for members of the Military, Veterans, Reserves, National Guard, and military support groups. It is also a chance for those at each location to hear and exchange messages of appreciation with each other over the radio. Many of us have friends, relatives, and neighbors that are active duty, and past members of the armed forces. ARMAD gives us the chance to support one another, and to express our thanks and appreciation to those that sacrifice and serve in the Armed Forces.

4002. Re: 5/8 wave 2 meter antenna matching

Newsgroup: rec.radio.amateur.antenna
Date: 2005-03-21 02:19:27 UTC
From: John Doe <JohnDoe@0.0.0.0>
Message-ID: <423e2edf$0$29446$afc38c87@news.optusnet.com.au>
Source record: 80446

Yes Roy,
A bit off topic on my part for the 5/8 on 2M.
But as you described the step down character of
the auto-transformer so well, I though you may wish
to add a description on the on the step up characterises.

Now I understand what you're describing. That could match an antenna
having parallel transformed feedpoint R less than 50 ohms and moderate
capacitive reactance. But it's probably not the best way to do it. You
couldn't feed a 5/8 wave vertical this way, because the parallel
transformed feedpoint R is greater than 50 ohms. The portion of L below
the tap would be the value needed to resonate with the equivalent shunt
Xc of the antenna. Then the additional turns would simply be the rest of
the autotransformer to step up the equivalent parallel feedpoint R.

4003. physical 1/4, electrical 1/2 wavelength

Newsgroup: rec.radio.amateur.antenna
Date: 2005-03-21 02:26:42 UTC
From: John Smith <assemblywizard@gmail.com>
Message-ID: <d1lbhb$pj0$1@domitilla.aioe.org>
Source record: 80447

My question(s):

For an example, on the 10 meter band:
If I take a 28" whip and mount it at the end of helical wound coil (wound on 1" diameter form), where the "wire length" of the coil, PLUS, the length of the whip (28" + coil wire length) is equal to 1/2 wavelength (electrical length)--BUT, the overall physical length of the antenna (top, tip of whip to base of helical wound coil) is 1/4 wavelength, what would the radiation pattern of such an antenna be?

Would it favor the pattern of a 1/4 or 1/2 wave antenna--or, would the pattern be a compromise between the two--or, would the pattern be totally unrelated to either?

What could I expect the impedance of such an antenna be? Would the reactance be capacitive or inductive? What would be the best way to provide a match to 50 ohm coax from such an antenna?

What software is available to model such an antenna?

Thanks in advance,
warmest regards

If you wind, say, 100 inches of wire into a coil, it doesn't act the same as 100 inches of straight wire. And no two different coils wound from 100 inches of wire will act the same. A coil's radiation characteristics are very nearly the same as for a wire the outside diameter and length of the coil, not the length of the wire it's made from. And the inductance of the coil is dictated by the length, pitch, number of turns, and diameter of the coil, not the length of the wire it's wound from. So your question can't be answered unless you tell us the diameter of the coil and any two of length, pitch, and number of turns; or the length and diameter of the coil and its inductance at the frequency at which it's being used.

4007. Re: physical 1/4, electrical 1/2 wavelength

Newsgroup: rec.radio.amateur.antenna
Date: 2005-03-21 08:17:25 UTC
From: John Smith <assemblywizard@gmail.com>
Message-ID: <d1lvuk$84o$1@domitilla.aioe.org>
Source record: 80452

OK, if you notice in my post wire length is in quotes, i.e. "wire length."
In the example, it is a given that this length resonates at 1/2 wave along
with the combined length of the whip (hence, electrical 1/2 wavelength.)

So, your post, while presenting individual points and your opinions, in
general--seems to answer very little, if any, of the original questions
raised--and certainly cannot be accused of containing any specifics.

The diameter IS stated (1"), the wire length is the lenght of the wire minus
28 inches which is necessary to be a resonate 1/2 wave, AND this is divided
over (1/4 wave at 10 meters - 28 inches.) to arrive at the coil length--the
pitch is calculated from the coil length ((1/4 wave @ 10 meters) - 28
inches) and the wire lenght divided by pi (number of turns) spread out over
the coil ENTIRE length. And, of course, coil length plus whip length is a
1/4 wave.

If you refer back to my original post, you will see all of this IS there...

However, critical analysis is a wise beginning of any quest for answers.

Regards

Roy's answer is right on the mark.
The length of the wire is of no help in answering the question.
You are confusing mechanical lengths with electrical lengths.

Nigel

I've been gathering parts so I can make a WiFi site. I dont know enough about wireless to offer any help with that part. But, I do have some experience with parabloic antennas. Contact me thru my E-mail if you are interested in trading thoughts.

Jerry

Hi John,

This appears to be a difficult question to answer, if for only all of the extraneous details. Patterns are determined by the physical size in relation to wavelength. It is all about geometry and distances between what are called current nodes - what you describe has no s in the node(s), so the geometry (pattern) is still quite simple.

Obtain a free copy of EZNEC to confirm.

A few further comments.

For perfectionists, the attenuation along a twin-line wound on a choke balun, is appreciably less than a coaxial line of about the same length.

This is due to the lower Zo of the coax and also due to the very small inner coaxial conductor diameter and its higher loss resistance.

This is not of great conseqence. The length of line involved is quite small anyway. Less than 1/8th wavelengths at the highest frequency of interest.

The power-handling and voltage-handling ability of twin-line is also greater than coax line.

So, in general, a choke balun wound with Radio Shack, 18 SWG speaker cable, is cheap, easier to construct, works better, and is more power efficient than the small-bore coax usually used.

Hi Nigel,

All parabolas have the same formula, simply different constants (size). If you want more gain, build a larger parabola. There is some diminishing return because your actual antenna is not getting larger, and a lot of the gain from the ends would be reflecting into unoccupied space.

I would offer one caution. The "template" offered appears to have a geometrical distortion from being stored for printing vs. stored for viewing (it appears to be squashed from either side, as viewed at the page).

As for a formula, that would be far more complex than construction instructions:
1. Obtain a large sheet of graph paper;
2. Along its longest edge, rule a line;
3. In the middle of this line, extend a perpendicular line;
4. Along that perpendicular mark a focus point (5 inches would do);
5. Along that perpendicular, halfway between the line in 2. and the focus in 4. mark one point of the parabolic surface;

This defines the hallmark characteristic of a parabolic surface, ALL points lie equidistant from a perpendicular line from 2. and from point 4. Your graph paper should provide a lot of perpendiculars from line 2. to use as guides. This will be cut-and-try until you get the hang of it:

A. Select one perpendicular graph line and mark a point out X inches;
B. Using a compass, measure from focus point 4. X inches;
C. If the compass can touch the mark A. you made a lucky guess;
D. Mark this A. as another point along the parabolic surface.

However, luck is not always with us, and the compass either overshoots A. or undershoots it. Move A. and adjust the compass equally until they both match. Repeat A through B along other perpendicular lines and eventually you will have a rough trace of a parabolic surface. Connect the dots and smooth the line.

I need to buy an external High Gain Antenna to plug into my mobile phone. I need to operate the phone in a very remote area, where the signal is at best, only one bar on the display. I will mount the antenna on a pole on the roof, so I will need advise on cable as well. Can anybody tell me where to buy such a beast, thanks.

4017. Re: physical 1/4, electrical 1/2 wavelength

Newsgroup: rec.radio.amateur.antenna
Date: 2005-03-21 18:39:51 UTC
From: John Smith <assemblywizard@gmail.com>
Message-ID: <d1n4dqvmg1@domitilla.aioe.org>
Source record: 80463

The original post is a math problem--its "solution" is an antenna. It is structured as a "word problem", as opposed to a math problem written using digits and numbers--for the most part--only coil diameter, whip length and wavelength (both physical and electrical) are expressed as numbers. Most will be familiar with this from high school or college mathematics. However, since this alone seems to be such a matter of confusion, let's look at the problem and rely on more numeric means of expression-using only the information from my first post.

1) top whip length = 28 inches

2) coil diameter = 1 inch

3) physical coil length = (1/4 wavelength - 28 inches)

4) antenna physical length = 28 inches + coil length

5) "wire length"(whip + coil wire length) = electrical wavelength

6) number of turns = (wire length / (pi(3.14159) * coil diameter(1 inch)))

= (wire length / 3.14159 inches)

7) pitch = number of turns spread/spaced over the ENTIRE (helical) coil length

8) antenna is end fed at the base, EFWHA-a vertical monopole

9) The antenna's physical length is wave on 10 meters but, is a wavelength electrical length on 10 meters.

NOTE: Please feel free to critique/correct any errors I have made in the above, no offense will be taken (but, arguments may be posed!)-indeed, this stands in regard to all my posts.

My questions, defined in greater detail, were/are:

1) What would the radiation pattern of such an antenna be-favor wave? Favor wave? A hybrid pattern of and ? Or, would it be unique pattern onto this antenna alone, and only vaguely reminiscent to one or the other, or both? (And arrived at by math, charts, measurement or other means which provide "proofs."

2) Would this antenna display a reactance which is capacitive or inductive, or purely resistive (and what proof(s) confirms this?)

3) What would the impedance of this antenna be? (Even a ballpark figure-within 5%-10% but, derived though math, chart or direct

measurement-NOT a guess?)

4) What method of matching this antenna to 50 ohm coax would be "best?"
(Capacitive hats, l-network, pi-network, balun (unun in this case), &#65533; wave
line, combinations of these schemes, etc.?)

5) Is there software capable of modeling such an antenna constructed under
these specifications (I have mmana but am unable to grasp how it could be
used for such a design?)

Certainly no disrespect was meant in my response to Ray's comments. Indeed,
if I "miss-treat" individuals I don't expect I will get ANY interaction from
them-this is NOT my purpose or intent! And, if you re-read my second post,
I complement him on his critique of the problem and his analytical powers.
In my neck of America, if someone attempts to set up conflict over verbal or
text exchanges, we generally consider him/her to be a "chit stirrer."

If my intent is NOT clear, let me try again: This is simply an excursion
into the exploration of an antenna design and its' properties. If you are
intent to read other goals into my posts-you are on your own!

I totally expect only those with knowledge, skills and investigative minds
to bother in this endeavor and, some will not even see reason to ask these
questions at all-one can probably be purchased off a shelf-somewhere in the
world.

Warmest regards

Assuming equally efficient feeds, nothing.

It is diameter in wavelengths that determines gain.

Changing the "pointyness" just changes the focal point, which may cause
gain problems due to practical problems with providing a decent feed, but
doesn't change gain.

A few options here...

- NVIS.or short skip distance use only. A 3 element yagi has what, a 120 degree lobe? I did some experiments a long time ago with a quad on 27MHz with it pointed up at about 60 degrees. Stations about 300km away were real good but almost no locals. Have to be a very good ionospheric day of course.

- Speaking to ET's (of course)

- The whole thing was fed as a phased array or the lengths of the Di/Re were varied to give a broadside pattern. (Or an experiment with same)

- There were some low flying but stupid Galas in the area (pink & grey parrots) that along with chewing coax also had a very set flight plan that the operator was trying to dodge..

One of the funniest things I saw was the expectation that a yagi mounted real close to the ground or roof was actually going to perform well..
A good example of this is one mounted 6-12" above a rotary clothes line.

> "Occam's razor is not always sharp"

Nope.

The maximum theoretical gain of any parabola is determined by the diameter in wavelengths.

The things than subtract from the maximum gain are the surface accuracy, both in terms of how close the curve is to a true parabola and any surface "bumps", and the illumination of the feed.

Irregularities in the curve and "bumps" less than about 1/8 wavelength have little effect, bigger than that and they can have significant effect.

The pattern of the feed (the feed itself is an antenna and has it's own pattern) determines the illumination.

The feed is mounted at the focal point of the parabola.

A "flat" parabola has a longer focal point than a more "curved" one, to use your terms.

If the pattern of the feed is such that it just exactly and perfectly illuminates the whole reflector, you get maximum gain.

If, as in the real world, the pattern of the feed spills out beyond the edge of the parabola or doesn't fill the whole parabola, you get less then the maximum theoretical gain.

The ARRL antenna book has a pile of equations, tables, and graphs showing these relationships and how to make working parabolic antennas.

Source record: 80471

The use of "wire length" to describe the antenna impedance made it diffiicult to understand what you were asking, and certainly deflected my thinking. If you had only said that the coil had the inductance necessary to make the antenna half-wave resonant (or antiresonant), it would have been more clear. On re-reading it, I see that it's what you meant, and it's what you did say in a slightly unconventional manner. So that gives enough information for at least some general answers to your questions:

>>>to base of helical wound coil) is 1/4 wavelength, what would the
>>>radiation
>>>pattern of such an antenna be?
>>>
>>>Would it favor the pattern of a 1/4 or 1/2 wave antenna--or, would the
>>>pattern be a compromise between the two--or, would the pattern be
totally
>>>unrelated to either?

It would have a pattern very similar to a quarter wave vertical, not a half wave.

>>>What could I expect the impedance of such an antenna be? Would the
>>>reactance be capacitive or inductive?

The resistance would be high, on the order of a couple of thousand ohms or more. If the coil resonantes the antenna, the feedpoint reactance, by definition, is zero. However, a slight deviation of the frequency from resonance will result in a fairly large reactance. It will be inductive below resonance and capacitive above.

What would be the best way to
>>>provide
>>>a match to 50 ohm coax from such an antenna?
>>>

Connect one conductor of the feedline to the antenna base, and tap up the helix with the other until a good match is achieved. This requires that the antenna be resonated with the coil.

>>>What software is available to model such an antenna?
>>>

EZNEC is able to do it. The demo program could be used to make an approximate model with the inductor modeled as a number of lumped loads along the wire. With the standard or plus programs you can model the inductor directly as a wire helix. I develop and sell EZNEC, so I'll leave it to others to recommend other programs -- I believe there are

several which can do the job.

In the example being discussed, the feed antenna appears to be an
omnidirectional vertical attached to an 802.11 access point.

In this particular case, because the feed has an omnidirectional
pattern, it seems to me that there would be a definite advantage to
using a relatively "deep" and thus somewhat "pointy" parabolic
section, in which the focal point lies a fair distance back from the
forward-most edges of the actual reflector.

This would tend to increase the portion of the feed antenna's omni
pattern which actually illuminates the reflector and is focused in the
forward direction.

Using a more shallow parabolic section, and getting high gain out of
it, would require a modification to the feed antenna so that it
illuminated the reflector more efficiently, with less spillover. I've
seen some designs for 802.11 which use a fairly shallow dish (with the
focal point well forward of the edges of the reflector), illuminated
by a feed antenna which is either a two-element dipole+reflector or a
"backfire" patch antenna.

I don't know whether it's feasible to make such a non-omni-feed design
as inexpensively as the "cardboard, tin foil, standard access point"
designs posted on the Net.

Hi Nigel,

As you may observe, their description exactly matches my instructions.
All Parabolas look the same, it is merely a difference in constants,
and the constants in this regard are explicitly stated as the variable
"a."

Change "a" and hold "L" constant, and you have identical gain in the
direction of interest (perpendicular to the directrix).

The only question left unresolved is do you choose graph paper from an
8x11 tablet, or from a newssheet sized tablet? Same instructions for
either, the sheet from the larger tablet (larger "L") yields higher
gain in the direction of interest (perpendicular to the directrix).
Choose any "a" dimension you care to for aesthetics sake only.

In the case of an omni vertical, it would be easier to construct a
corner or trough reflector with a ground plane and it would probably
work better since the bottom half of the parabola (or full corner
reflector) most likely won't be illuminated anyway.

Nigel -

A very good technical resource is the Green Bay Professional Packet Radio
group.
http://www.qsl.net/n9zia/

You may not be aware that amateur radio (FCC Part 97) actually shares a
portion of the
802.11 "WiFi" (FCC Part 15) spectrum allocation.

Well Roy (sorry I mis-spelled your name as Ray in a post above), you are not the first to bring it to my attention, the fact that my manner and methods are "unconventional", indeed, some have not been no kind and have referred to me as eccentric! <grin>

As I type this, I am downloading a demo of your EZNEC program. I will spend a little time with it and see if I can get the hang of it and, how to describe the antenna problem to it. Quite possibly it will provide me with answers, or even (and quite hopefully!) provide me with new questions.

Thank you for your time in responding and, if I have offended you, as some others have pointed out may be the case, I apologize, I am sincere when I state that was not my purpose...

Warmest regards!

Absolutely Richard! It does seem difficult with available tools--at least
without building it and even then putting much labor into expermenting,
testing, pruning and adjusting...

Yet, it seems like such a design would suggest itself to many minds and be a
good solution to many restricted spaces and, one does ponder why the math,
methods, formulas, software, etc. has not been created to make such a matter
of childs play--and well documented and explained.

Many mobile whips seem centered around designs somewhat similiar to the one
proposed. And, indeed, I have seen a few expermentally inclined hams
goofing around with similiar designs for shack antennas on the long
wavelengths, just wish I had paid more attention at the time....

I am a capable C/C++ software engineer (professional hacker) and am
constantly searching for ideas to put to code to feed my personal
interests...

Warmest regards

Hi John,

In fact, nearly every "new" idea that hits this board can be found
described with utter simplicity - years ago (10, 20, 40, 80 years).
Very little math is demanded and the record is full of documentation.

The continuous length of coil you describe has been anticipated by one
in using a "slinky." The benefit there is that the springy form
allows one to collapse or extend the coil to find resonance. Use two
of them and you have a dipole.

It performs, and has performed for years. You can buy one too. Why
doesn't everyone use one? The reason goes back years ago to rather
simple terms: size v. wavelength and the number and separation of
nodes. It performs, but not as well as a larger antenna it attempts
to replace. Hence: size v. wavelength is a restriction, there is only
one node, and it has nothing (another separate node) to combine with.
Once you can get your arms around these simple concepts, then you
throw in loss - the numbers get ugly and the pain is real.

We get tons of small antennas touted here.

>Many mobile whips seem centered around designs somewhat similiar to the one
>proposed.

However, among the population of those many, when they are all
compared the longstanding traditional designs win hands down. They
win for very simple reasons. The list of rules, so to speak, is very
short.

Unfortunately there are too many simple reasons floating around as new
and improved theory. The test of the newcomer is to separate those
improved theories (noted for their baroque language, elaborate math
and lack of field work) from ages-old results nailed down in rather
ordinary terms.

The new-and-improved theories call upon
- separating the E and M fields;
- unique properties of fractal math;

- improved length efficiency;
- proofs of polygonal analysis;
- super gain;
- over/tight/critical coupling;
- faster than light transmission....

As you can see, the field of simple reasons abound. Some reasons have their attractive features, but once you try to pull the conversation into the realm of implementation, barriers to discussion bloom like weeds.

Most mobile phone accessory shops have external antennas for sale. These antennas are designed for use in a car, but work fine without. The cable is not very long (2-4m), but adding a chunk of 50Ohm RG58-type cable is possible. I'd cut the cable close to the antenna to preserve a decent bit of the original cable (with the connector matching your phone) on the phone side for comfort.
If you know where the closest base station is than you can add a parabolic reflector and aim for it to increase the signal. Just google for wifi and parabolic and scale according to the frequency you use. If you are using the 800 or 900 Mhz bands the reflector can get quite large though.

Well... Yes, that argument is made with most everything...
It has already been done... everything has been tried... all the answers are known... there is nothing new to be found out...
(But, just on the outside chance that thinking is wrong: What about LDE (long delay echo)? You got the answer to that?)
The fact is, most, if not all, of the formulas we deal with are crafted from things we have first built--THEN we look for a mathmatical explanation to explain the object we built. While this is better than nothing, it is slow--exploration by first developing the theory and math--then the physical object--is much more suited for really finding "something new" and the rapid development of such objects. (i.e., computers design computers, however, since antennas can't design antennas--we need computers to design the antennas.)
Unfortuantly, if all we use are past "rules" and "laws" we can only find the past!!! Anything REALLY NEW will break all the laws we are currently slaving under (or, at the least, re-define these laws) with total disregard to the high esteem we had held these faulty laws.... indeed, being too tied to the past and "conventional thinking" may hold us to the past...
However, whenever there seems a danger of this happening, then someone comes in from left field with a new idea, such as quantum physics, and all bets are off, and the physists and mathematicians are sent off to develop new, undenighable and final laws to explain it...

If it were all done, if there is nothing new to be found out, if all the existing data and formulas are totally all there is... WHY THE HELL ARE WE HERE? Let's go buy one, go home and have a beer...

Fact is, we hate to admit when we are wrong, so, when we are wrong we quickly move on and say these NEW ideas are what we have really believed all along!
I am not opposed to the possibility that all that can be known, is known... however, some guy that doesn't know any better usually suddenly pops up and you end up embarassed for your beliefs--one more time.

The fact is, I have built those "silly antennas", by hand, with real materials--then modeled them on mathmatical models, evaluating what is actual against what was predicted... few ever provide anything but disappointment. But, I am convinced that while what the developers are claiming may be "false reasoning" and improper models, there is something here which has been overlooked and current conventional thinking and models miss...

However, the antenna design I presented is simply a helical loaded 1/2 wave which just happens to correspond to 1/4 wave physical length...
It really doesn't challenge any current antenna theory or present anything

new, other than perhaps an unconventional arrangement of wire...

Frankly, I take it as a "leap of faith", but as long as there are
discussions such as these... something new is comming our way right now, we
just won't be able to see it till it gets closer, then we will realize we
really "knew it all along!"
But then the harsh "reality" hits us, we realize and with some
disappointment--that once again it has happened, all the final answers and
laws are known--nothing to do but go home and grab a beer and wait for next
time... <grin>

Warmest regards

Is there a rough calculation on how high I should be aiming to mount
the Antenna (law of diminishing returns, and all that). A half
informed friend said I should use a YAGI antenna, is he correct? If so
where do I buy a suitable one in the UK or Europe for Spain.

I know where the base station is, where do I buy a parabolica to
match, how does one mount the Antenna on the parabolica? what size
dish is a good size to start with? would an old TV Satellite dish do
it? Do I ground the dish?

Not even close. Prime focus parabolas (and offset fed) are defined by their F/D (focal length to diameter ratio). A "deep " dish would have an F/D of 0.3 or less. Shallow dishes 0.6 or greater. The real problem here becomes the ability to properly illuminate the dish with a feedhorn. Typical scalar feeds will be efficient from 0.3 to 0.5 or so. Under illumination can mean better G/T but you are likely not using the all the surface. Over illumination results in seeing warm earth noise and degrading G/T.
Do a Google search of W1GHZ site- an excellent tutorial on passive reflectors and feeds.

Hi Dale,

What feed horn? Let's stick to what is and not what might be. A
dipole is perfectly capable of seeing any surface generated even if it
is not particularly the most optimized focus.

Besides, this is hardly on the scale of 10-24GHz and all such
discussion presents Point Locus Parabolic Reflectors. The original
poster is seeking a obtainable goal, not a theoretical maximum. The
discussion of his provided links show a simple achievement of 10dB
which is not shabby by any means.

I try those angles, and go the extra mile. Evidence some 300+ pages
of examining fractal antennas:
http://www.qsl.net/kb7qhc/antenna/fractal/index.htm

This work eventually boiled down to a simple conclusion (not that the
leading proponent would allow his mystical explanation to be nudged
into the corner of drab insight).

These days I usually put a filter into the process by asking the
"inventor" a simple question:
Does it bring more than 1dB gain with it?

Hi Richard,
I have worked with parabolas for years- the current dish is a 14' w/ 0.36 F/D and illuminated with a scalar feed. A dipole is perhaps one of the worst feeds for a parabola. If you're going to put the surface up why not take full advantage of it? It takes little if any additional work to properly illuminate it.

Well... yes... and no....
In investigating small antennas, my quest was not to find antennas which preformed within 1 db as well, as well, or God forbid, better than their full sized counter parts.
Rather, I was looking for antennas which preformed better than the poor preformance which standard theory would suggest--a simple suggestion that the theory was in error and, hopefully ones which could be utilized with acceptable results in restricted spaces. Both of those condidtions I did find!
While a pocket antenna which would preform as well as a half wave antenna on low freqs (or any freq for that matter) would be fantastic, I lack the faith to believe it possible--except at multiple Ghz, where both become the same!
However, it is very possible you might use the pocket antenna in places where you could never never use the halfwave.
And of course, under such conditions--I would want the best possible pocket antenna which could be constructed!

Warmest regards

Well, let me just post this at the bottom. RCA made a line of VHF TV transmitting antennas which were a slot arrays. The only one I managed to get close to before it became airborne and clamped a thousand or more feet in the air was for
channel 9. It was 80 feet long (2 - forty foot sections) and was constructed exactly as Tom, K7ITM suggested, the phase
of the feed of each element was progressively changed, in this case, to effect 1.5° of downtilt. I would suggest contacting RCA TV antenna engineering for their design parameters, but they seem to have gone somewhere.

"Standard theory" has been around for over a hundred years now, and is the basis for the design of some millions of antennas used for everything from your cell phone to communications beyond the solar system. Laboratories world wide measure antennas daily which have been designed with "standard theory", and in those past hundred years plus, no one has found any credible evidence that "standard theory" is in error. Of course, charlatans claim it almost daily, just as they claim the discovery of perpetual motion but inevitably their claims are shown to fail in objective tests.

Backyard tinkerers love to fantasize that they'll be the next Galileo and in a few hours, days, or years, make the breakthrough discovery that shows all them eggheads a thing or two. It's pretty easy for such a person to convince himself that he's done just that, because accurate antenna measurements are much more difficult than amateurs generally appreciate, and the sources of error are often subtle and require knowledge of basic theory to understand. Another common basis for a shouted "Eureka!" is a lack of knowledge of "standard theory", and the gee-whiz revelation that what the discoverer mistakenly thought was true turned out, after all, to be false. Clever ways of applying "standard theory" to make an antenna that's more useful in some way for some application are found frequently. Genuine evidence that "standard theory" is wrong has happened virtually never in the past many decades. The odds are heavily against the new Galileo springing up from the suburbs. My money's sure not on them.

People truly wanting to make a better antenna would better spend their time learning "standard theory" and less time tinkering in ignorance of it.

EZNec will model your antenna. As for the antenna, I believe that the
shortened 1/2 wave antenna will radiate with less effect than a
stretched 1/2 wave, but possibly better than a 1/4 wave. How much?
That depends on the coil and the matching network pending losses.

Good luck,

We had 1 degree of down-tilt on the RCA Slot antenna for Channel 11.
Unfortunately I got the task of Replacing Slot covers on the antenna which
at the time was 15 years old. The antenna was retired 2 years ago, it was
33 years old...

I was 21, and stupid enough to climb a 1000' tower.

I should add that the antenna you described will be less efficient than a plain wire of the same height. The use of the coil in place of a straight piece of wire:

1. Makes no substantial difference to the pattern shape.
2. Decreases the efficiency.
3. Potentially makes matching more difficult.
4. Unnecessarily increases cost and mechanical complexity.

But it might look groovy and impress the good buddies. And it might *seem* to work better -- the placebo effect is genuine and quite powerful and it's been the reason for a lot of satisfied customers.

Message-ID: <d1ob11$gs5$1@domitilla.aioe.org>
Source record: 80395

Well, I have 3 test antennas on this project:
1) 1/4 wave stainless steel whip w/4 heavy 1/2 inch, aluminum ground plane radials
2) 1/2 wave without any ground plane/counterpoise, lower 1/4 wave section is 3/4 copper pipe, upper 1/4 is a stainless whip, total of the combination is 1/2 wave... ferrite beads are used on the outer shield of the coax at the point where it connects to the antenna, match is though a simple l-network (ferrite beads are actually un-needed but used anyway, no real detectable radiation from coax either way)
3) This is the antenna I described in the first post(s), I tend to refer to as the "quarter/half", it is constructed on 3/4 ID pvc pipe, and has an OD of just over an inch, the coil is constructed of #8 copper wire and the top whip is the 28 inch stainless whip I mentioned. Is a resonate 1/2 wave and physical 1/4 (whip + helical coil length.) Matching network is a l-network, capactior is constructed of acrylic insulator plates (acrylic "window pane") with copper sheet plates, coil is a 1.3 OD torroid. coil is approx. 1+ uh (computed from toroid data)--I have not measured the capacitance of the capacitor (probably somewhere from 20+ pf to 30+ pf), no groundplane/counterpoise, ferrite beads as above.

Naturally, as the models predict, the 1/4 is lower in preformance than the half 1/2, and very noticable in the most distant contacts.
However, the "quarter/half" out preforms the 1/4 but falls lower in preformance than the 1/2. Contacts out at 30+ miles are where the electrical 1/2 wave antennas differ most from each other (antennas 2 and 3 above.)
FSM measurements of the two 1/2 waves are very simuliar--however, these measurements could have been taken at a greater distance to increase accuracy (meters sensitivity I currently am using limited this.)
Franky, I was surprised by the preformance. As others have predicted--I expected the preformance of the shortened 1/2 wave to be poorer than the 1/4 (mainly due to the helical coil skewing the radiation pattern and adding a slight resistance to a physical 1/4 antenna.)
However, it seems to fall in the middle between the 1/4 and the 1/2 wave (full length) antennas, favoring being closer to the 1/2 full length by 1/2 S-unit+
The biggest difference between the 1/4 and 1/2 wave full length is 2-3 s-units at stations in the 30+ mile distances.
The full 1/2 wave and the shortened 1/2 wave seem close to 1 s-unit on all apparent distant stations.
I find this hard to believe, and the models I calculated did not reflect what I had actually seen in s-units.

All three antennas were placed at the same height, on the same mast while testing (32 ft above real ground.) And all other conditions the same.

The l-network match is the only difference between the two 1/2 wave
antennas, in the future I will correct this and finalize the tests... the
difference in the matches could be responsible for the difference in
expected results.
Right now, it actually looks to me, from the above--that the "1/4 physical,
1/2 wave electrical (quarter/half)" antenna was and is exhibiting properties
of both a 1/4 and a 1/2 wave antenna. This is the main reason I tossed out
this "antenna problem" here, to see others reactions and draw from their
experience.

Warmest regards

Hi Dale,

Well, I described how to build the reflector, you can describe how to
build the horn. Myself, I think that at 900MHz that is where the
trouble is going to start as the horn will almost certainly shadow the
reflector that already gives him 10dB gain.

Now if Nigel is trying to stretch Wi-Fi into Wi-Max, then such an
investment may be opportune.

A specific vendor I cant help you with then (I am in Australia)

I would think that many large phone accessory distributors could sell you one. Otherwise look at some more professional antenna manufacturers. They often have yagis available in the phone frequency range. Take care with finding the right connector and keep the coax loss low.

It might also be cheaper to get a simple mobile gain antenna and mount it high. Get it clear of ground clutter and dont be afraid to move it around for the strongest signal (before bolting it in place)

You'll need to know the operating frequency of your phone. If it is a multi band thing you'll have to find the freq of your nearest node. This will also determine the coax loss/cost as well. I would suggest that if you are running 10 metres or so to use LMR400. It isnt the lowest loss cable around but it is still easy to terminate and seems to have the best cost/loss numbers. There are a number of sites around that allow you to calculate cable loss at specific frequencies. Of course it also depends on whether it is available where you are.

To give you an idea a 10m run of coax at 900MHz with LMR400 is about 1.3dB loss. Using RG213 the loss is about twice that and the cable cost is higher! RG58 has a whopping 5-6dB loss. I find it strange that mobile phone antennas have such horrible cable.

Hope this helps

Cheers Bob

4055. Re: physical 1/4, electrical 1/2 wavelength

Newsgroup: rec.radio.amateur.antenna
Date: 2005-03-22 08:40:50 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <113vmgocegae0cf@corp.supernews.com>
Source record: 80398

If there's no ground system loss, a half wave vertical antenna has about 1.3 dB gain over a quarter wave vertical due to the sharper pattern shape. This is the line-of-sight or surface wave gain difference. If reflection from real ground is included in the analysis, the gain difference is about 1 - 1.5 dB at lower angles, and the quarter wave does much better, by 3 or 4 dB or so, at high angles (very roughly above 50 degrees or so).

Coil loading to achieve half wave resonance does have one potential advantage, and that's to reduce ground loss when substantial ground resistance is present. Because of the much higher base impedance, ground current is much less with a half wave resonant base fed antenna than with a quarter wave antenna, even when the resonance is achieved with coil loading. Ground loss is typically pretty low on ten meters in mobile applications, but in some other setups (such as ground mounting over a buried radial system, or a hand-held radio), the reduction in ground current could reduce ground loss more than enough to compensate for coil loss.

I suspect this is the explanation for at least some of any advantage you see in the coil loaded antenna over a straight wire of the same length. However, there's a good sized handful of other possible factors. (Every last one of them, incidentally, explainable perfectly well by "standard theory".) If the measurement results don't agree with the model, it nearly always means that the actual antenna -- that is, the "antenna", the "ground" system, and everything connected to either one or in the near field of either one -- differs from the model in some significant way. Or the measurement system is faulty.

Someone interested in understanding the operation of an antenna will commonly spend a great deal of time tracking down the factors that differ between the model and real antenna, and it's just about always a truly educational experience. When done, the result is usually a model that really represents the antenna system, and that shows results very close to careful and competent measurements. And an experimenter who knows more about antennas, modeling, and the importance of some factors he never before considered. You go through this exercise a few hundred times, like professional engineers routinely do, and you come out with a great respect for "standard theory" and an even greater level of skepticism toward people who have a weak understanding of it and are convinced they've witnessed a miracle. Those of us who have spent a career using "standard theory" to design real, useful items that work as designed haven't become skeptical because our brains have been petrified by education; it's because we've seen "standard theory" work, over and over and over, and every last miracle inevitably fall, one after

another, to careful scrutiny and understanding.

But we also eventually come to realize that astrology, homeopathy, and feng shui(*) will be with us forever. People will simply believe what suits them, and won't be bothered by evidence. Especially if the evidence takes effort, knowledge, patience, and understanding to acquire.

The "S-Unit" is a nice homey amateur unit of measurement, but it has no meaning. (Some people seem to think it's equal to 6 dB, but vast numbers of others think it's the the size of the markings on their receivers' "S Meter". The two can be very different.) dB, on the other hand, is a universally defined and understood unit. Anyone unable to accurately measure relative values in dB is unable to make quantitative gain measurements at all.

(*) My spell checker didn't recognize this, so I did a quick google search to see if I got it right. It came up with 2,180,000 hits. There's no lack of believers.

> lose a contest?
> Reg, G4FGQ

This post started with a question about a 28" loaded whip operating on 10 meters, presumably to be used in a mobile application. The concern of the post was how to model the antenna to determine whether it would have the pattern of a 1/4 wave or a 1/2 wave vertical radiator.

But for a mobile application the affect of the auto body, the local environment, and even the direction the car is pointing can alter the free-space pattern of the antenna more than the difference in the relative radiation patterns of 1/4-wave and 1/2-wave verticals -- and particularly so for VHF/UHF antennas.

If 1dB of antenna gain is so critical to amateurs, suggest that more attention needs to be paid in its system design to the operating environment of the antenna. Some NEC programs make it fairly straightforward to model the net patterns of antennas as mounted on vehicles, and should lead to a better understanding of antenna performance in the real world.

> constructed exactly as Tom, K7ITM suggested, the phase
> of the feed of each element was progressively changed,
> in this case, to effect 1.50 of downtilt.

The antenna described above is the RCA "Traveling Wave" design. Without beam tilt for the situation described, it has an omni, horizontal plane RMS gain of ~17.2X (~12.4dBd) . The beam width within the 3dB points on its elevation pattern is about 3.2 ï¿½.

If this antenna was placed with its radiation center 1,500 feet above smooth earth, the radio horizon would be 0.59ï¿½ below the horizontal plane, so using beam tilt would raise field strength there. The 1.5ï¿½ value stated above exceeds that, but there may have been good reasons for it.

Adding beam tilt to an antenna with a very broad elevation pattern, and installed on a short tower is a waste of time and money, however.

This post got me to thinking (always dangerous)

Whatever happened to that wunderantenna from the University of Rhode
Island?

ttp://tinyurl.com/5qn4d

Especially interesting is the comparison against a 5/8th wave antenna @
150 MHz. Presemably that antenna was matched by a 9 inch DLM.

The BW was apparently 1 MHz better than the 5/8th wave, although thte
sentence was a bit unclear with that respect.

I remain very skeptical.

Bogus or Bonanza?

You said you made your antenna with a base loaded coil and added an L-matching network. I have been reading the ARRL manual which says that the center loaded coil produces a different current curve and a better match.

Assuming that the L-network produces some (any) loss, the better match will theoretically overcome that. However, the inductor has to be considerably larger and inductors are somewhat lossy.

Has anyone tried, and/or can anyone model this version to see how it compares?

Yes I used to work for the company many years ago the main transistors
were:-

OC171 the 4 lead type.
OC71 (I think)
And OC81 for the main amp. (if my memory is correct that is)
The Mk II had a 470 Khz trap on the front end.
The IF stages were double tuned at 470Khz
And a filter at 1000Khz for the audio. At least thats what I remember
of the Mk II.

The BFO was rubbish to say the least.
I found it hard to resolve many signals that were to strong.

If you scrapped the paint of the plastic type OC71 you then had the
equivalent of an OCP71 phototransistor
which IIRC were at least 4x the cost of an OC71 ! Bargain !

nostalgia ain't what it used to be.....

4078. Re: physical 1/4, electrical 1/2 wavelength

Newsgroup: rec.radio.amateur.antenna
Date: 2005-03-22 21:18:43 UTC
From: John Smith <assemblywizard@gmail.com>
Message-ID: <d1q23l$ko1$1@domitilla.aioe.org>
Source record: 80415

Absolutely, and, "If it works don't complain!", is my motto.
Still, my mind ponders and responds with questions...

One thing I haven't been forth coming with is the 1/4 wave antenna. Really, I don't know what specs a "proper" one should be constructed to (working off very basic ARRL diagram).

The one I built has a very heavy stainless whip--most likely is military surplus, but years ago I bought a whole slew of them and still have not used them up, the whip base is about 3/8 and tapers at approx. 12 feet to a 3/16 dia.

I just hacked it to a 1/4 wave with the 1/4 ant length formula provided by the ARRL book and removed length with a very course file, until resonate. The radials are 1/2" aluminum rod and heavy. The insulating material for the whip is cut from 1-1/4" thick nylon sheet. The SWR was originally high, but "drooping" (ARRL book suggested this) the ends of the radials, down near a 45 degree angle, provides 1:1.5. The radials are cut 5% wave longer than the whip (again, suggested by ARRL book), they are grounded to the mast and the mast has a good earth ground. Antenna is directly fed with 50 ohm coax.

Perhaps my construction of the 1/4 is less than optimum? And, this may make it appear that the antenna from my original post is performing better than it really is.... <thoughtful frown>

The weather here is high wind and rain. I will not be tempted to do any more experimenting until this passes...

Regards

Hey! If you can't provide and suggestions, how about just spell checking this for me?

Art Unwin wrote:
"I have just come to realize that if one drew a polygon of element phases in an array and all elements were 180 degrees to its companion element and excluding its driven element, the max gain and max front to back will occur at the dame frequency!"

I missed a step or two between the polygon`s resultant and coincidence of maximum gain with maximum front to back ratio.

A vector has both magnitude and direction. A scalar quantity has only magnitude.

Vectors are represented by arrows whose lengths correspond to their magnitudes. Directions of the arrows correspond to the directions of the vectors.

The combined effect of two or more vectors is called a resultant. A resultant can be found by a geometrical rule called vector addition. Vectors are placed head to tail while maintaining their magnitudes and directions. The resultant is a vector drawn from the tail of the first vector to the head of the final vector. Any number of vectors can be added by the head to tail method. These can create a polygon of vectors.

If only two vectors are to be added at a time, they can produce a resultant by the parallelogram method. Two sides of the parallelogram are formed by the two vectors connected at their tails. Parallel same length sides are added to form the parallelogram. A diagonal emanating from the junction of the two vectors forms the resultant

When one vector (call it c) is the resultant of two vectors (call them and b) we can say that a and b are components of c. Any given vector can be resolved into an infinite number of pairs. Usually we find it convenient to resolve a vector into a pair which are at right angles with each other. Then we can use the Pythagorean theorem (c squared = a squared + b squared) to find the magnitude of the resultant (c).

In a right triangle in which two sides are perpendicular, all the trignometric functions are useful in determining the lengths and directions of its sides.

Best regards, Richard Harrison, KB5WZI

Hi Richard,
Depending on surface size, that may be correct. An offset dish and an 0.7F/D
horn would avoid that problem. Without doing the math, the now defunct- and
available fro free, Primestar 1M offset dishes may be an excellent solution.
Then again, if he only needs 10dB, a small loop yagi could serve with a lot
less surface area.

Buck,

I disagree with you on this. If the coil does indeed resonate the antenna in 1/2 wave, antiresonance, current distribution will be different than the straight quarterwave resonance. The current maximum will occur in roughly the center of the loacing coil length with a current minimum at the bottom. Since photon generation is an ampere/length concern, there must be a greater peak coil current to achieve the same power radiated. That would probably incur greater losses than quarter wave resonance.

The half wave resonance might have an advantage if there is a problem achieving an adequate counterpoise under the antenna for normal quarter wave resonance. A lot of through-the-glass mobile antennas have been sold using this principle.

I wonder if Roy has a simple way to include the coil Q or losses in the EZNEC model. I'm sure there is a logical way to work it out but I haven't had time to think it through yet.

Thanks for checking in, Richard.

Please refresh my admittedly fuzzy memory from 40+ years ago. Did they (RCA) not adjust the phase delay by using
different lengths of dielectric in the inside between adjacent sets of slots? Allowing one size (per channel) of
radiator, but allowing selection of downtilt after machining of the exterior. Or was that Dielectric's design? And,
that particular antenna never worked to expectations, and I always said I thought it had too much tilt. And indeed it
had an extremely strong signal on the ground near the tower. Much more than any other installation I ever visited.

P1-9-1324 back then.

Hi Dale,

But this does not answer the problem of the horn design.

As I see it, a simple waveguide (no flared horn) itself will run
something like 6" x 12". About the size of a shoe box. Adding the
flare will probably quadruple that area. Now, to build an offset dish
will force a rather more difficult reflector design project. The
irony is that simply turning the horn around and using it would
probably do just as well, but unfortunately be more cumbersome to
construct and use than the simple design already linked to.

As for the Primestar dish, that is undoubtedly a Point Locus Parabolic
Reflector design that would clash with the geometry of its 10 times
larger intended application. This does not bode well when the appeal
is efficiency based.

Even the style of the classic pringles-can-array is probably simpler
to achieve than horns combined with offset dishes. [However, probably
closer to Crisco Can sized weighing in at several pounds.]

Quick Moral, The first 6 to 10 dB is the easiest gain to achieve.

4084. Re: Down Tilt on Slot Antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2005-03-22 23:39:22 UTC
From: Richard Fry <rfry@adams.net>
Message-ID: <4240acff_4@newsfeed.slurp.net>
Source record: 80333

The interior of the VHF TW antenna essentially is a 50 ohm center conductor against the ID of the pylon. Beam tilt is done by the location of the slots on the pylon. The useful part of the elevation pattern of these antennas is made very smooth (no sharp nulls), and it produces fairly uniform fields near the ground from close to the tower base on out toward the radio horizon.

The antenna was designed by RCA (Gibbsboro), and the design and production facilities for it were acquired from them by Dielectric when RCA folded in the mid-1980s.

As for the effects of beam tilt, Figure 1 in paper #9 at http://rfry.com gives a graphical representation and discussion of what can be expected.

P1-8-3246 (1950s).

Do you really think an antenna using entangled electrons
can be predicted by "standard theory"? :-)

Sure. If modeling it as a helix, simply specify wire loss for the type of wire or plating on the wire used for the coil. (The loss in the coil will be much greater than the loss in the straight wire, so it's no big deal if the straight wire is made from some other material.) If modeling it as lumped loads (not as accurate), include the appropriate value of R in the loads. You can quickly and easily see how much loss the coil is causing by comparing gain with the loss present and absent.

A few experiments showed a pretty close agreement between EZNEC's helix model with wire loss and Reg's inductor program with regard to L, resonant frequency, and Q. I didn't, however, run tests with a wide range of coil geometries and wire sizes.

The EZNEC helix model will underreport loss if wire spacing is less than one or two wire diameters, since it doesn't account for proximity effect (uneven current density around the wire).

Although you can manually (and tediously) build a helix model with EZNEC v. 3.0 or EZNEC-ARRL which is v. 3.0, or create one with an external program and import it, EZNEC v. 4.0 has a built-in helix creation feature that generates a helical coil with a few keystrokes.

"John Smith" wrote, " Rather, I was looking for antennas which preformed better than the poor preformance which standard theory would suggest--..."

Perhaps you're thinking of different antennas than I have in mind right now. But using simple resonant half-wave dipoles or quarter waves over ground planes, it seems to me the performance is pretty amazing. Consider that under the right HF skip conditions, you can communicate half way around the world with such antennas, fairly simple receivers, and just a few watts of RF. Put the same amount of RF into a transmission line made of copper wires and consider how far it gets before the power is too low to be useful for communications. Even if your transmission line were extremely low loss (say 2.5cm diameter wires forming a 600 ohm line, giving about 0.15dB/mile at 4MHz), in under 2000 miles, you wouldn't have enough power left on the line to give reliable communications. And the antenna-radiated RF would be detectable over a wide area, not just at the output of a transmission line. Even fairly small antennas, half or a quarter the size required for unloaded resonance, can be efficient enough to allow pretty remarkable transmission of RF energy. In fact, the inefficiencies of small antennas generally come about in the matching systems much more than in the radiating structure itself. So I'm left wondering just why you think antennas that perform as "standard theory" suggests are performing poorly.

Or perhaps you're considering the difficulty of concentrating the radiation in a certain direction using small antennas...though I would not have thought that from your base posting.

Cheers,
Tom

4093. (yet another) transmission line question

Newsgroup: rec.radio.amateur.antenna

Source record: 80328

More for the fun of pondering it than for any immediate practical
reason...

If I make a balanced two-wire transmission line from round wires, and
I'm constrained to have the wire center-to-center spacing some
particular value (say one inch, or five centimeters, or whatever), what
wire diameter should I use to get the lowest matched-line loss? What
impedance line does that give (assuming air dielectric)?

Clearly for a given wire diameter, the wider the spacing the lower the
loss up to the point where radiation plus dielectric loss becomes
significant, but I can imagine situations where you want to limit the
wire spacing and get low loss.

Cheers,
Tom

Absolutely...
Even though it is only necessary to deliver mere nano watts to the receiver on the other end, the atmospheric sphere, combined with the magnetosphere, around this planet is/are an amazing means of conducting rf for communications.
And the ducting of vhf and uhf can appear to be even "magically" efficient at times.
There was some guy from germany, old ex-postal worker as I remember, never did well in school, and never spoke a word till the age of four, quite a while back now--who claimed it all relative... he might have been right...

At least on the last paragraph- agreed.
On the Primestar, I have sued this on 10GHz with a feed designed for high
F/D with very good efficienvy. Being offset, the feed does not eclipse any

portion of the dish.
There are a couple of new designs for feeds out- one is a square guide that does not require a scalar for choking off edge currents. My version at 1296 has an inside dimension of 5.75" and would then be 1/2 this for 2.4 GHz- or about 6 " SQ inches of occupied space. A 1M dish would have approx 1200 SQ", so even in a prime focus configuration, the feed blockage is a non- issue.
In the final analysis though, I'd go with a parasitic design- bogner or loop yagi. Too high a gain can also be a pointing issue problem.

Well....
I could have stated a less controversial design I guess.
Such as an antiresonate antenna cap--folded from aluminum foil, and intended to cancel out the moon bounced mind control rays from the aliens.
Since totally shielding the walls of my home with silver foil has failed to block the penetration of these "antenna rays" into my home, the cap might be just the ticket!
The burning question here would be what wavelength of foil the cap should it be folded from, and heck, I don't even think the frequency of their mind control rays registers on earth meters!
It is a conspiracy, I TELL YA!!! <grin>

Unless I goofed up the math (a distinct possibility), the answer is that you want a Z0 of about 144 ohms, which is a spacing/diameter ratio of about 1.81.

This was pretty easy to solve via differentiation using the approximation Z0 ~ 120 * ln(2S/d) where S = the center-to-center wire spacing and d is the wire diameter. The answer I got was 120 ohms, or d = 2S/e, or S/d ~ 1.36. Unfortunately, this spacing is too close for the approximation to be accurate, so the answer wasn't good. When I used the full inverse hyperbolic cosine formula for Z0 and took the necessary derivative, I found the resulting equation too messy to solve in closed form. So I went brute force and used a simple program to iterate and spot the maximum. It looks to me like you need to maximize d * Z0 in order to minimize the loss (see below).

Don't trust my answer without some checking -- I did it pretty quickly so there's lots of room for error.

It's good to have an opportunity to dust off the neurons once in a while. Thanks.

Loss per unit length = attenuation constant alpha = 1/2 * (R/R0 + G/G0) nepers/m. With air dielectric, G ~ 0, so alpha = R/(2*R0), where R = AC resistance per meter (both wires) and R0 = (assumed purely real) Z0. Assuming skin effect is fully developed, R ~ k / d where d = wire diameter and k depends on frequency, resistivity, and permeability of the wire but not on d, S, or Z0. So alpha = k / (2 * d * R0). This shows that minimizing alpha (loss) requires maximizing d * R0, which appears to occur when R0 ~ 144 ohms (S/d ~ 1.81).

Being you want to go both directions, you will probably need to
use a compromise spacing that affords near equal gain in both
directions...Naturally, this will compromise maximum gain, but
not too much you can do about that, being in one direction you
will be running a broadside array, and the other, an endfire array.
The spacings for max gain are quite different for each type.
In general, max gain for a broadside array is about 5/8 wave
spacing. An endfire array, somewhere around 1/8 wave. So I'd
probably use something like a 1/4 wave spacing to make both
directions appx equal gain. You could model this, if you wanted
it real close...Naturally, on other bands, this will all go
out the window...But if you used the 1/4 wave spacing on 40m,
at least you could run an endfire array on 80m, using the close
1/8 wave spacing. The max gain of a wide spaced broadside array
is slightly higher than the max gain of a close end fire array.
But if you fed with a wider 5/8 WL spacing for max broadside gain,
it will be too wide to feed as a decent endfire array in the
other direction."2 db less than 1/8 wl spacing"
You could feed with 1/4 wave spacing for 80, and have 1/2 for 40,
but ditto again..You will lose a bit endfire.."about 1.5 db less"
If you use 1/4 wl spacing , the difference between the two
directions will be only about .5 db using 90 and 180 degrees
phasing , for broadside, and then endfire. You can try other
phasings and get even more patterns...
There are graphs in the antenna handbook.
Also, there are articles in the antenna handbook on
how to feed them. The simplest method I use, just being changing
feedline lengths...You don't really need a phasing line, per
say...IE: if you want to feed one element 90 out of phase from
the first, just add 90 degrees "1/4 wave" of extra feedline to
the second element ...Consider the velocity factor, etc...
There is plenty of info on all this in the ARRL antenna handbook.

Actually, and back to reality:
I am in the San Joaquin Valley in California, while this used to be one of the richest agricultural areas in the world, decades of double and triple farming has depleated the soil of many of the plentiful nutrients (salts, trace minerals, metals, etc.)
Also, this area was like a tule swap before levies were built to hold back the water, i.e., a peat bog!
Those who mentioned a poor and lossy ground condition might have something there...
This area may naturally favor the 1/2 properties.

But then too, maybe it is only those damn aliens with their mind control which are placing these ideas in my head! <grin> Yanno, agriculture uses a lot of those darn illegal aliens' labor!!!

As he says, Roy's resulta are very approximate. That's mainly because he neglected proximity effect between the wires.

A better approximation is obtained by incorporating an approximate expression for proximity effect. However, this makes differentiation of the loss formula with respect to wire diameter ridiculously tedious. So I found minimum loss by plotting a graph with a pocket calculator and searching for it.

At HF when skin effect is fully effective, and neglecting dielectric loss in comparison with conductor loss -

For a fixed wire spacing, as wire diameter increases, the wires get closer together and proximity loss eventually increases faster than ordinary loss decreases due to the increase in diameter.

Thus minimum loss occurs at a smaller diameter and a greater Spacing/Diameter ratio. The Ro at which minimum loss occurs is independent of both frequency and wire conductivity. Results are -

Ro = 177 ohms. Spacing between wire centres is 2.29 times wire diameter.

Which demonstrates that mathematics is vastly superior and takes priority over practical experiments and making measurements.

From an engineering point of view, K7ITM asked the wrong question. He should have asked, for a given wire spacing, what wire diameter minimises the cost of the copper. Or something like that.

Many years back a similar sort of calculation was done for coax. Coax does not suffer from proximity effect. It's easier to work out. The answer was 75 ohms. That's how 75 ohms became the standard comunications Ro. There are many millions of miles of the stuff. The Chinese are now making even more of it.

Without line amplifiers across the USA, if all the energy output from the sun was sent into one end of the phone line, only one electron in a thousand years would trickle out of the other end.

I have done the same when sending a reminder email to myself, and gotten back "xxxxxx@taring.com - invalid user". .com is pounded into our brains.

There's a picture of the Plexiglasï¿½ panel on my web page that
was taken ten years ago in Arizona and I'm still using it.
It's the 1/2 inch thick stuff, is still in good shape, and
is still performing its function perfectly. My Piper Plastics
properties chart says the effect of sunlight on Acrylic is "nil".
The main reason that I used acrylic was - it was a 50 cent piece
of stuff from the odds and ends box at a plastics place in Phoenix.
I also used it and some acrylic rods to build an air-core mobile
loading coil about 15 years ago. That coil is still in good shape.

> On the othe hand, Lexan (trade
> name) is polycarbonate, which is very durable.

Yep, Lexanï¿½ is the stuff used in Airplane windows and is easy
to machine. It is superior to acrylic in every way. If I had
used polycarbonate, it would probably still be performing its
function perfectly. (My '96 GMC Sierra Pickup with 180,000 miles
on it is still performing its function perfectly. :-)

Maybe it's the same as the parallel tuning coil installed
at the base of a 75m mobile antenna which has a real part
equal to 12-25 ohms (depending on the quality of the antenna).

I vaguely remember something about efficiency Vs power
handling capability being the difference in the 75 ohm
standard and the 50 ohm standard. Is that right?

EZNEC comes with VERT1.EZ, a 40m vertical. I just ran it
at 19 MHz and EZNEC reports a 50-j160 ohm feedpoint impedance
with a maximum gain of 2.23 dBi and a TOA of 16 deg. Seems all
that is needed for matching to 50 ohms is a series base coil.

Page 5-15 of The ARRL UHF/Microwave Experimenter's Manual says:

"Consider that both power handling capability and cable losses vary with Zo.
It has been shown that cable losses are minimum at a characteristic
impedance on the order of 75 [Ohms], while power handling capability is
maximum at a Zo of about 30 [Ohms]."

(The book used the Greek symbol rather than [Ohms])

The quoted passage is in a chapter by Dr. Paul Shuch, N6TX, Professor of
Electronics, Pennsylvania College of Technology. At the end of the quote, is
an indication to see footnote 13 which is:

"Moreno, Theodore, Microwave Transmission Design Data, Dover Publications,
1948."

Message-ID: <42419b8e$0$3708$39cecf19@news.twtelecom.net>
Source record: 80359

I have a coworker that would like to put up a 40m antenna on his tower
that has some gain and directivity. I have modeled a few things, and
while they are fairly satisfactory, I wanted to see what ideas the group
had.

The approximate limitations are as follows -

o Boomlength 30 feet
o Element length 30 feet
o Any vertical components are max -10 feet from the plane of the boom
and elements. The reason here is that it's a crankup, and his roof
clearance would be about 10 feet when lowered.

It would be desirable to have both CW and phone covered, but phone only
is ok.
It will need to be coax fed.

Thanks.

There was an article in QST (IIRC) in the last decade and a half (IIRC)
about selectable phasing. The coax to _both_ verticals - of equal
length - were brought into the shack. These were attached to the ends of
a multi-position switch - and then sections of coax were daisy-chained from
switch position to switch position. The coax to the xcvr, then, was
connected to the rotary position of the switch. At least, IIRC. HI!HI!

That seens exactly right. It`s the reason you would use 75-ohm Zo cable for TV distribution at low-power where you want to minimize loss but there is no danger of too much voltage flashing over the cable.

Terman in his 1955 edition on page 106 says:
"---in an air-insulated coaxial line of given outer radius b, Q will be maximum when the inner conductor has a size such thet b/a = 3.6. (b=inner radius of outer conductor in concentric line, and a=outer radius of inner conductor in concentric line) corresponding to Zo = 77 ohms. These are also the proportions for minimum power loss----."
However the maximum power that can be transmitted without exceeding a given voltage gradient occurs when b/a 1.65, giving Zo = 30 ohms."

So for minimum loss you would want Zo of about 75 ohms and for maximum power capability you would want 30 ohms. I suspect Zo=50 ohms is a compromise between power handling capability and reasonable loss.

Best regards, Richard Harrison, KB5WZI

4118. Loading Coil Q

Newsgroup: rec.radio.amateur.antenna
Date: 2005-03-23 17:56:34 UTC
From: Buck <iam@this.site>
Message-ID: <uca3419vpurnm4a9dddrtk6s0hveh3uqti@4ax.com>
Source record: 80363

I have aluminum poles of three diameters, 1.5, 1, and .5 inches. I have enough of the first two to create a pole of about 15 feet each and about 8 to 9 feet with the 1/5 inch poles. The poles are no more than 4 feet long each, but they are able to tuck inside each other, at least for the same diameter.

What I want to do is to make up a 'kit' with these that I can take to the field to setup whatever antenna I want to use at the time. For example, I might set it up as a 20 meter vertical in one configuration, but in the evening, I might reconfigure it to 75 meters or 15, or 30 or whatever I desire.

One consideration is to create a high-q coil for it. I am thinking of using 1/4 inch copper tubing to make a ten to twelve inch diameter coil so I can match it to the lower bands. I have been reading that base loaded coils have to be matched to the antenna, but center loaded verticals are more closely matched to 50 ohms. from what I have been reading, the center loaded coil requires more turns and a top loaded coil even more.

A capacity hat is also a viable option.

I am wondering how much I am helping or hurting myself with the larger coil or if I would be better off with a smaller coil. One thought is to connect x number of poles, then the coil, then another set of poles or a whip to make the final adjustment for the match or to match the antenna by tapping the coil.

I am open to all suggestions, but I am interested in knowing the best location for the coil and the best size for it.

Thank you

If you use an "L" network consisting of two inductors as a matching
device, the R must be less than 50 ohms. I was incorrectly modeling
the tapped coil as a two inductor "L" network.

==========

It is unreliable to use ARRL and similar publications as Bibles. They are written by amateurs for amateurs and tell only a sufficient fraction of the whole story. Phrases such as "It has been shown that .... " arise. They also refer to UHF/Microwave when LF and HF are of interest. At microwave frequencies the dielectric loss cannot be considered negligible.

For minimum attenuation, air-spaced coax Zo = 75 ohms and D/d = 3.6
For solid polyethylene Zo is smaller.

Confusion about the value of Zo which maximises power handling capabilty arises because coax cables have different shapes and materials to support the inner conductor. Even though the dielectric may be considered lossless its presence affects matched line loss.

If my memory serves me correct, for maximum power handling I think 50 ohms refers to air-spaced coax and 30 ohms or thereabouts refers to solid polyethylene dielectric. Or it may be the other way about. It will be different again for a different dielectric permittivity.

For a coax line used as a tuned circuit, eg., when short-circuited, maximum impedance at resonance occurs when Zo = 132 ohms and D/d ratio = 9.1

And just to add a little more to the confusion, whether the outer conductor is solid or braided also makes a small difference.

Reg, G4FGQ

Actually, the problem as I posed it is from an engineering point of view, assuming that a particular constraint dominated the problem...well, actually I had in mind stating it as wires that would fit inside some diameter, but that complicated it more than I wanted as an exercise for this group. Engineers should first ask what the goals and constraints are, and the space the wires fit into may be one such constraint. I suppose minimum copper cost would be the smallest wires (that could handle the required power)!

A starting point for a more complete problem statement from an engineering point of view might be, "Minimize total system cost, expressed in net present value, of the system over its operating life, under a particular set of performance and installation constraints."

Thanks, though, for your consideration of proximity effect. Without that, I got the same answer as Roy, and appreciated Roy's inclusion of the basis on which he made the calculation.

I'd point out that for coaxial cable construction, a particular D/d minimizes the loss for a given D, and a different D/d minimizes the electric field strength for a given power and therefore maximizes the power handling capability of the line in the case where the line is voltage-limited (generally low duty cycle pulse operation), and yet another D/d minimizes the peak electric field strength for a given voltage applied to the line. So long as the dielectric loss is negligible and the dielectric is uniform, all those D/d ratios are independent of dielectric fill. The D/d which minimizes loss is close to the D/d which maximizes power handling capability of the line, if the line is power-dissipation limited, but not exactly so because it doesn't consider how the center conductor gets rid of its heat. The minimum attenuation (if the inner and outer conductors are the same smooth material and skin depth is small compared with the thickness of each) is for D/d = 3.5911, which as others have pointed out yields about 76.7 ohms with air dielectric, but if the dielectric is solid polyethylene, it's about 51 ohms. If the center conductor is smooth copper and the outer is corrugated aluminum, the minimum-attenuation D/d increases. If the dielectric is foamed polyethylene, that pushes the impedance back toward 75 ohms.

Cecil...if the line is limited in power handling by its temperature rise (which is almost always the case, except for low duty cycle pulses or line construction that's very different from what we commonly use), the minimum attenuation configuration will also be the minimum net dissipation configuration, and therefore close to the optimal power handling capability. As an example of how cables we commonly use are

thermally limited, consider that solid-dielectric RG-213 at 40C ambient
and at 10MHz is rated at about 2kW. At 50 ohms, that's only 316 vrms
for a CW signal, and RG-213 is rated for use up to 5000 vrms, which
would 250 times as much power (so it better only come in little short
bursts that don't overheat the line). That "power handling is maximum
for Zo=30 ohms" thing is ONLY good if the line is limited by voltage
breakdown, not by temperature rise! It IS useful--in radar systems,
for example--but you must be careful to understand your application.

Cheers,
Tom

Richard Fry wrote:
"This post started with a question about a 28" loaded whip operating on 10 meters presumably to be used in a mobile application."

As Richard Fry noted, the vehicle and its position affect the antenna`s pattern. Also at 10 meters, a 1/4-wave whip would be little more than 8 feet long. A 28" whip is less than 1/3 a resonant length. Capacitive loading to make up the missing length is probably impractical. A loading coil is lossy but practical. Best choice is likely the 8-ft whip. A CB whip can be trimmed to resonance on 10-meters.

If one wanted an antenna to fit between poles about 1/4-wave apart, one could use a 1/4-wave folded dipole, which is resonant due to its 1/2-wave circumference. Gain is only 0.5 dB less than a full 1/2-wave dipole. Like a small loop, the small folded dipole can be resonated with a high-Q series capacitor. Arnold B. Bailey in "TV and Other Receiving Antennas" gives the resistance of the 1/4-wave folded dipole as 6000 ohms at center frequency. This would require transformation to a lower impedance. Another resonant antenna that fits a 1/4-wave space is square and 1/4-wave on each side. It`s about 35 feet of wire for 10 meters and has a feedpoint resistance of 100 to 200 ohms depending on its height over the earth. Over good earth, feed one of its vertical sides in the center. Over poor earth, feed a horizontal side in the center. See ON4UN`s "Low-Band DXing" Chapter 10 for details on large loops.

Best regards, Richard Harrison, KB5WZI

Program LOADCOIL models short, coil-loaded, vertical antennas.

Amongst other things it allows the coil to slide up and down the antenna (from the keyboard) and find the coil location at which power radiating efficiency is maximised.

The best location depends on antenna dimensions, coil dimensions and ground loss resistance ohms, and is very non-critical. Top loading is never the best.

Download program LOADCOIL in a few seconds from website below and run immediately.

> base loaded coils have to be matched to the antenna, but center
loaded
> verticals are more closely matched to 50 ohms.

The loading coil is used to tune out the capacitive reactance.
The input impedance will vary to length of the vertical, coil loss,
ground loss, etc..Just because a center load is used, doesn't always
mean the input impedance will end up 50 ohms..

from what I have been
> reading, the center loaded coil requires more turns and a top loaded
> coil even more.

Yes.
>
> A capacity hat is also a viable option.

It's the best option. And top loading is best using capacitive
loading, where as if using a coil for top loading, the coil losses
overshadow any increase in efficiency from the improved current
distribution, etc.. Top loading using wires is the best system you
could use, if you can swing it.
>

> I am wondering how much I am helping or hurting myself with the
larger
> coil or if I would be better off with a smaller coil.

It's not that critical...

One thought is
> to connect x number of poles, then the coil, then another set of
poles
> or a whip to make the final adjustment for the match or to match the
> antenna by tapping the coil.
>
> I am open to all suggestions, but I am interested in knowing the best
> location for the coil and the best size for it.

The *best* location for a loading coil is appx 2/3 to 3/4 up the
radiator. But even half way up is fine. Base loading is the least
efficient, and has the worst current distribution. But it uses the
least number of coil turns, and would have the least coil loss.
Being low, it's the easiest to adjust also...
Don't forget that the ground system for a short loaded vertical,
becomes even more critical than for a full 1/4 wave vertical.
It's for this reason that I usually avoid verticals for portable
use, unless the ground issue can be dealt with. IE: at the beach
is a good place for verticals...But in the boonies, on lossy, rocky,
ground, they may not do so hot if you have no radials. In that
case, I would take the vertical "sticks", and hang a dipole from
them...:/ My mobile antenna is my usual "portable vertical"...MK

Okay, Reg, then go read the material referenced by footnote 13. That's one reason I included it. Maybe that way we won't need to rely on your memory.

John

4127. Re: (yet another) transmission line question

Newsgroup: rec.radio.amateur.antenna
Date: 2005-03-23 23:45:59 UTC
From: Reg Edwards <g4fgq.regp@ZZZbtinternet.com>
Message-ID: <d1sv3n$n6k$1@titan.btinternet.com>
Source record: 80372

```
Provided skin effect is fully operative, ie., skin depth is about
1/6th wire diameter or less, proximity effect increases wire
resistance by dividing normal skin-effect resistance of a single
straight wire by K :

K = SquareRoot( 1 - Square( D / S ) )

where D is wire diameter and S is centre-to-centre wire spacing. Note
that resistance increases towards infinity as the pair of wires
approach contact with each other. This is confirmed by precision
measurements.

To minimise line attenuation for any given wire spacing, maximise U
with respect to D :

U = D * InvCosh( S / D ) * SquareRoot( 1 - Square( D / S ) ) .

4128. water proof swr's?

Newsgroup: rec.radio.amateur.antenna
Date: 2005-03-24 02:34:27 UTC
From: ml <m@di.net>
Message-ID: <m-3A00CA.21342023032005@news.verizon.net>
Source record: 80373

hi

larger swr's bother me, if you can bare w/my ramblings i wonder f
anyone might have some useful tips...

i have a center fed dipole mounted on some pvc w/eyebolts .

previous rains/snows didn't really effect my swr's

accross 6-160m my swr's were usually 1:2 maybe 1:4 on one band.

thanks to the mast mounted sgc237 feeding my dipole via 5' of ladderline

its a short dipole 25ft hot side about 40ft rf 'gnd' side.

today i guess the snow was wet and trees, n stuff are all coated
w/thick ice, can't see my antenna, but guessing it might have the
center part frozen?? and or other parts. (not my dipole is roof mounted
and clear of trees)

on most bands starting at 18mhz and lower my swr are now anywhere from
1.5 to about 2, not terrible, but not great(good as b4)

so my question is , does anyone know of any tricks that might prevent
ice from altering the swr's, anyone try plastic coatings that repel
ice or 'hoods" guessing they'd have to be far or would just form a ice
hat?

my center is spaced just about 1 1/4" the dia of my pvc pipe and only
slightly larger than my 450 ladder,, would it make sence to make the
top of my ladder line wider spaced ie increasing the gap between the 2
dipole halves? to minimize ice?? i am guessing that creating this
larger 'gap' would increase my ohms maybe this would be bad

thanks

4130. Want Money? Try This

Newsgroup: rec.radio.amateur.antenna
Date: 2005-03-24 04:49:51 UTC
From: gh <ghernandez46@mailblocks.com>
Message-ID: <1111639791.277460.277060@f14g2000cwb.googlegroups.com>
Source record: 80374

Quick Easy Cash

: LOTS OF CASH, FAST AND COMPLETELY LEGAL, THIS REALLY WORKS!!
: THIS REALLY CAN MAKE YOU EASY MONEY!! IT WORKS!!! BUT YOU
: HAVE TO FOLLOW IT TO THE LETTER FOR IT TO WORK!!!!
: A little while back, I was browsing through newsgroups, just like you
are now, and came
: across an article similar to this that said you could make thousands
of dollars within weeks
: with only an initial investment of $6.00! So I thought," Yeah, right,
this must be a scam",
: but like most of us, I was curious, so I kept reading.
: Anyway, it said that you send $1.00 to each of the 6 names and
address stated in the
: article. You then place your own name and address in the bottom of
the list at #6, and
: post the article in at least 200 newsgroups. (There are thousands) No
catch, that was it.
: So after thinking it over, and talking to a few people first, I
thought about trying it. I figured
: what have I got to lose except 6 stamps and $6.00, right? Like most
of us I was a little
: skeptical and a little worried about the legal aspects of it
: all. So I checked it out with the U.S. Post Office (1-800-725-2161)
and they confirmed
: that it is indeed legal! Then I invested the measly $6.00. Well GUESS
WHAT!!... within 7
: days, I started getting money in the mail! I was shocked! I figured
it would end soon, but
: the money just kept coming in. In my first week, I made about $25.00.
By the end of the
: second week I had made a total of over $1,000.00! In the third week I
had over
: $10,000.00 and it's still growing. This is now my fourth week and I
have made a total of
: just over $42,000.00 and it's still coming in rapidly. It's
: certainly worth $6.00, and 6 stamps, I have spent more than that on
the lottery!!
: Let me tell you how this works and most importantly, why it
works....also, make sure you
: print a copy of this article NOW, so you can get the information off
of it as you need it.
: A cousin of mine did this a few months back, and he is now enjoying
life in his brand new Tahoe Sport!! ($30,000+). So it does work!!

: STEP 1: Get 6 separate pieces of paper and write the following on
each piece of paper
: "PLEASE PUT ME ON YOUR MAILING LIST." Now get 6 US $1.00 bills and
place
: ONE inside EACH of the 6 pieces of paper so the bill will not be seen
through the
: envelope to prevent thievery. Next, place one paper in each of the 6
envelopes and seal
: them. You should now have 6 sealed envelopes, each with a
: piece of paper stating the above phrase, your name and address, and a
$1.00 bill. What
: you are doing is creating a service by this. THIS IS ABSOLUTELY
LEGAL! Mail the 6
: envelopes to the following addresses:
:
:
:
:
:
: 1- Kevin Klingelhoefer
: 615 Crescent St.
: Langhorne, PA 19047
: USA
:
: 2- A.L.
: Rimon 631/24
: Natzareth illit, T.D. 13123
: ISRAEL (17000)
:
: 3- Jeremy Franklin
: PO Box 11
: McCune, KS 66753
: USA
:
: 4- Wallden Enterprises Inc.
: 14329 - 68th Avenue, Surrey, B.C. V3W 2H5
: Canada
:
: 5- Frank Gomez
: 11108 Shoreline Dr.
: El Paso, TX 79936
: USA
:
: 6-G.H.
1011 W. Alberta St.
Anaheim,Ca. 92805
USA
:
: STEP 2: Now take the #1 name off the list that you see above, move
the other names up

: (6 becomes 5, 5 becomes 4, etc...) and add YOUR Name as number 6 on
the list. STEP
: 3: Change anything you need to, but try to keep this article as close
to original as possible.
: Now, post your amended article to at least 200 newsgroups. (I think
there are close to
: 24,000 groups) All you need is 200, but remember, the more you post,
the more money
: you make! ---DIRECTIONS -----HOW TO POST TO NEWSGROUPS------------
: Step 1) You do not need to re-type this entire letter to do your own
posting. Simply put
: your cursor at the beginning of this letter and drag your
: cursor to the bottom of this document, and select 'copy' from the
edit menu. This will copy
: the entire letter into the computers memory. Step 2) Open a blank
'notepad' file and place
: your cursor at the top of the blank page. From the 'edit' menu select
'paste'. This will paste
: a copy of the letter into notepad so that you can add your name to
the list. Step 3) Save
: your new notepad file as a .txt file. If you want to do your postings
in different sittings,
: you'll always have this file to go back to.
: Step 4) Use Netscape or Internet explorer and try searching for
various newsgroups
: (on-line
: forums, message boards, chat sites, discussions.) Step 5) Visit these
message boards and
: post this article as a new message by highlighting the text of this
letter and selecting paste
: from the edit menu. Fill in the Subject, this will be the header that
everyone sees as they
: scroll through the list of postings in a particular group, click the
post message button.
: You're done with your first one!
: Congratulations...THAT'S IT! All you have to do is jump to different
newsgroupes and
: post away, after you get the hang of it, it will take about 30
seconds for each newsgroup!
: **REMEMBER, THE MORE NEWSGROUPS YOU POST IN, THE MORE
: MONEY YOU WILL MAKE!! BUT YOU HAVE TO POST A MINIMUM OF
: 200** That's it! You will begin reciving money from around the world
within days! You
: may eventually wany to rent a P.O.Box due to the large amount of mail
you will receive. If
: you wish to stay anonymous, you can invent a name to use, as
: long as the postman will deliver it. **JUST MAKE SURE ALL THE
ADDRESSES ARE
: CORRECT.**
: Now the WHY part: Out of 200 postings, say I receive only 5 replies

(a very low
: example). So then I made $5.00 with my name at #6 on the letter. Now,
each of the 5
: persons who just sent me $1.00 make the MINIMUM 200 postings, each
with my name
: at #5 and only 5 persons respond to each of the original 5, that is
another $25.00 for me,
: now those 25 each make 200 MINIMUM posts with my name at #4 and only
5 replies
: each, I will bring in an additional
: $125.00! Now, those 125 persons turn around and post the MINIMUM 200
with my
: name at #3 and only receive 5 replies each, I will make an additional
$626.00! OK, now
: here is the fun part, each of those 625 persons post a MINIMUM 200
letters with my
: name at #2 and they each only receive 5 replies, that just made me
$3,125.00!!! Those
: 3,125 persons will all deliver this message to 200 newsgroups with my
name at #1 and if
: still 5 persons per 200 newsgroups react I will receive $15,625,00!
With a original
: investment of only $6.00! AMAZING! When your name is no longer on the
list, you just
: take the latest posting in the newsgroups, and send out another $6.00
to names on the list,
: putting your name at number 6 again. And start posting again. The
thing to remember is,
: do you realize that thousands of people all over the world are
joining the internet and
: reading these articles everyday, JUST LIKE YOU are now!! So can you
afford $6.00
: and see if it really works?? I think so... People have said, "what if
the plan is played out
: and no one sends you
: the money? So what! What are the chances of that happening when there
are tons of new
: honest users and new honest people who are joining the internet and
newsgroups everyday
: and are willing to give it a try? Estimates are at 20,000 to 50,000
new users, every day,
: with thousands of those joining the actual internet. Remember, play
FAIRLY and
: HONESTLY and this will work.
: Also, for the skeptics, you're looking at this and thinking about
doing it right? imagine
how many millions are looking and thinking the EXACT same thing

Good Luck

You can make a coaxial antenna using coax cable. Take RG-58 for
example. Cut off the outside jacket about 20 inches from the end.
Make a small hole in the shield brade and pull out the center
insulator and conductor. Cut both the center conductor and braid to
about 18 inches in length. Then tape the braid to the side of the
coax cable. Make some sort of hook on the top of the center conductor
and hook it, or maybe tape it, to a high place. The antenna will be
effectively a vertical dipole. They work great.

4133. More articles and new program now on web

I've uploaded two more articles to my web site:

"Antenna Feed Lines for Portable Use", from Technical Correspondence, QST, Feb. 1992. This includes measurements I made of 300 ohm twinlead which showed that it can become very lossy when wet. http://eznec.com/Amateur/Articles/Portable_Feed_Lines.pdf.

"The Simplest Phased Array Feed System - That Works", from the ARRL Antenna Compendium, Vol. 2. If you simply cut "phasing lines" to electrical lengths equaling the delay between elements in a phased array, you won't usually get anywhere near the phase delay you expect. You'll also get unequal element currents. The reasons for this are explained in Chapter 8 of the ARRL Antenna Book, and briefly in this article. The article shows how "phasing line" lengths which *do* work can be calculated, and new program Simpfeed (http://eznec.com/Amateur/Articles/SimpfeedZip.exe) does the calculations for you.

Wonder if you could keep spraying it to keep it wet while tuning, get an acceptable impedance match, and then perhaps see it improve as it dries? If, by any lucky fluke that worked, it might keep rain or ice from rendering the antenna unusable. You could try making it a little long and then a little short and testing both lengths wet and dry. At worst it might not improve in either case as it dries and you could go back to the standard tuning mode. It might be worth trying. I like antenna experimentation and, being retired, have all the time I need to experiment. (Money is my limiting constraint.)

ml,
I would think that it may be more trouble than it's worth. The
'trick' would be to keep stuff off of the ladder line which is the
problem (mostly).
One method I've found that works for me is to give the ladder
line a wack or two with a broom stick. Knocks the snow/ice off,
but (I probably have easier access to the ladder line than you do
since it runs from a window to my antenna :) .).
'Doc

PS - I'd rather move to Hawaii, but...

Hi Myles,

Water and Ice are not that big a deal when you have an SGC.

This and other SWR reports suggest your tuner is not taking care of
the job. You are not supposed to be seeing SWR. It sounds like you
don't have enough choking on the transmission line and/or the control
lines going up to your dipole. As pointed out before, trying to
obtain a total solution with one antenna MUST lead to some exceptions
in operation.

Thank you to Cecil, Reg, Mark, Asimov and Richard.

I have read what you said and done more reading about Cap Hats. The Cap Hat doesn't improve the inductor, it basically replaces it, at least in part, which removes the loss of the inductor. I misunderstood that somehow.

What I will focus on, then, is to create some form of capacity hat for each appropriate band together with an adjustable vertical length for tuning to the appropriate frequency.

Mark, You may have a point about the dipole being better, especially for portable operation. I just want to experiment with the aluminum poles I have. I may take your advice and use them to create a portable tower in the long-run. But first I think I will try out the vertical.

Thanks to all,

Buck

You could probably rig it up to do either, if the vertical
is stout enough to support a dipole/s. I have a couple of
drive on masts that I use with the fence rail masting.
Two of those makes 20 ft, and a good support for dipoles,
or other antennas. For industrial use, I have a tower and
beam I can drag around...I've drug it to the last four field
days...Wonder if I'm gonna make it five..?? It's a lot of
work for a two day deal....:/ I'm almost tempted to take a
field day vacation for a year...Have to see...MK

The confusion comes (in the quoting of the texts) because of a failure to consider that there are two different mechanisms that can limit the power handling capability of the line. One is power dissipation (temperature rise), and the other is voltage breakdown. Clearly the minimum power dissipation for a given input power and matched line occurs where the line attenuation is minimum. But if you make the inner conductor slightly larger, it may be able to get rid of heat enough better (for a given line construction) that the inner conductor temperature rise is slightly lower, even though the power dissipation is slightly higher. I would expect, though, that the optimal construction in most circumstances would result in an impedance only marginally lower than the minimum attenuation case, and the improvement would be a very small one. You'd have to convince me it was really important to get me to worry about it beyond just minimizing attenuation.

If it's voltage breakdown that limits the line power handling capability, the air-insulated impedance of the line will be at a D/d that results in about 30 ohms impedance for air-dielectric line, and .66 times as much for solid polyethylene line.

And if it's maximum voltage-handling you want, the D/d results in somewhere around 50 ohms with air-insulated line, about 33 ohms with solid poly, if memory serves. I could look it up if it's really important.

Generally in ham applications, (reasonably well matched) lines will be power dissipation limited, not voltage limited.

Cheers,
Tom

Considering that sometimes efficiency isn't quite as important, like
for example reception, are helical antennas less used simply because
the math is a little harder or not discussed enough? I recall seeing
this type being popularized during the old CB craze in the mid 70's.

Lately I've seen TV media trucks with a type of rather wide pole of
what seems to consist of a large coiled up ribbon. When they get to a
location they unfurl the tube and it raises the microwave antenna.
They seem to be made out of plastic or carbon, not sure. The one I saw
went up about 30 feet. It seems very lightweight in any case. Anyone
here know what it is?

From LF to VHF it is ALWAYS power dissipated in conductor resistance which limits the power handling capability of the line. Voltage has nothing to do with it. Above VHF dielectric loss becomes be the limitation.

Consideration of ambient temperature is vital. Are you located in Alaska at midnight in mid-winter? Or are you in the New Mexico desert in July, at noon. It makes hell of a difference?

With coax everything depends on the temperture softening point of polyethylene and on the the longer-term temperature deterioration (hardening, cracking, brittleness) of the PVC sheath.

Is the cable embedded in an asbestos insulated brick wall or is it suspended in free air with a breeze in the shade? Or in sunlight?

The power rating data provided by manufacturers for amateur grade coaxial cables is useless nonsense. From inspection of manufacturers' tables (watts) it can be deduced their ratings are based on the melting point of polyethylene. Salesmen's blurbs, no doubt plagiarised in ARRL publications, sound very good in order to sell the stuff.

To gain an elementary understanding of what it's all about, download in a few seconds, easy to use, practical application, small program "COAXRATE" from website below and run immediately. (Not zipped up).

Program "COAXRATE".

Always? Hardly. Transmission of pulses with low duty cycle will get you to voltage-limited operation pretty quickly. Transmission of power to a high-resistance load where the line is a very small fraction of a wavelength long may get you into voltage-limited operation. Those perhaps aren't typical ham applications, but they do happen in practice. Also, though the cable itself may not have trouble with the applied voltage, the connectors at the ends may. They're generally rated for much lower voltage than the line itself.

Also, for the small-diameter (nom. RG-58 size) cables I've been using lately, conductor loss exceeds dielectric loss out past 10GHz. YYMV.

Cheers,
Tom

Yep, during duststorms and thunderstorms, the connectors
arc. Arcing at the coax connectors of my IC-745, IC-725,
IC-706, and IC-756PRO has never seemed to injure any of
them. Is that just luck or are they that well protected?

Gary:

First, you are off by a decade, the Texas DPS moved from 1658 kcps. to 42.9 Mc. in 1949. Prior to the move, they used (very successfully, I might add) a earlier version of Reg's antenna, which was a 10 foot bamboo pole helically wound with waxed cotton insulated bell wire. IIRC, the winding was spaced about 1 to 1&#65533; wire diameters apart . The transmitter was directly connected to the base of the antenna with a short piece of 8 gauge wire, so there was no SWR to
worry about, and final tuning of the antenna was done in the transmitter output pi-network. Black '41 and '48 Fords with 10 foot cane poles on the rear bumper brackets, brings back memories.

I haven't actually tried it, but I haven't heard anything to indicate
a problem unless they are in beam formation in which one band becomes
a reflector in a higher band pending the spacing.

I would suggest spacing the elements 8 inches apart. That spacing
seems to make things work better than a closer spacing if the
antennas are parallel.

==========

Roy, having given a little more thought to it, I think that by differentiating U with respect to D and equating dU/dD to zero, things will then simplify and the value of the ratio S /D, and hence Zo, will be obtained directly.

If you still have enough enthusiasm I leave it to you to perform the differentiation.

Reg.

Hi:

That's called a "fan" dipole and it will work. A tip on tuning it up though, start with the lowest frequency antenna elements first and work your way up. There is ALOT of interaction between the elements in a fan dipole and the higher frequency ones are affected the most. If you put the elements at right angles to each other or as far apart as you can the interaction will be minimized. Because of the interaction between the elements the SWR bandwidth will be different than a single band dipole would be mostly less. Have fun!

Probably a collection of reasons. A high-Q loading coil in
the center of a vertical is much more efficient than spreading
the loading out over the entire antenna. Helical antennas are
hard to wind and are generally wound on PVC pipe which also
reduces efficiency and increases wind load. Even more efficiency
is lost without a good ground plane. If one doesn't compromise
on the ground plane, why compromise on the antenna? Most of us
old timers have tried helicals and given up on them - lots of
effort to achieve a poor performance.

Hi Jim,

The US National Electrical Code (NEC) is trademarked and copywrite property of the National Fire Protection association (NFPA). There is no official web posting of this information permitted. .

You may either purchase this information, visit your local library, or request help from readers of this group who may subscribe to the NEC and NFPA standards as I do. If you go to the library, also research Art 250 Grounding, and both 810 and 820. Various articles of the code are discussed in various electrical forums such as Mike Holt, et al.

Best regards,

Jack Painter
Virginia Beach, Virginia

==========

Wrong! Spreading a multi-turn coil allows a MUCH thicker wire
diameter to be used with spaced turns. Also the coil diameter can be
increased to minimise the number of turns.

Result : higher coil Q, lower coil loss, greater efficiency.

Dear "Asimov" w/o a call sign:

If you look closely, you will see that the "coiled up ribbon" is a
transmission line or a pair of transmission lines. By elevating the
antenna, which must be connected to the truck through at least one
transmission line, much improved transmission range is effected.

frequency-shift keying (FSK): A modulating scheme in which the modulating signal shifts the output frequency between predetermined values. Usually, the instantaneous frequency is shifted between two discrete values termed the "mark" and "space" frequencies.

Used to transmit digital data, i.e. two different carrier frequencies are used to represent zero and one.
FSK was originally used to transmit teleprinter messages by radio (RTTY) but can be used for most other types of radio and land-line digital telegraphy

Although this a form of frequency modulation (FM),
FM is usually thought of as a voice signal that modulates the carrier.

Got to disagree with you on that one, Reg. Mobile shootout
field strength measurements put all the helicals, no matter
what wire diameters were used, considerably down from the
well-designed bugcatchers and screwdrivers. That meter of
wire in each turn of the helical has more resistance than
the centimeter of radiating bottom section that it replaces
at the feedpoint.

It is well known and accepted that moving the mobile loading
coil from the center of the antenna to the base will reduce
the efficiency even though the inductance required for loading
is decreased. With a helical, part of the loading coil is
at the base and that's simply a bad idea when efficiency
is important.

One mobile, in particular, should have performed well. It
was made from 1/4 inch copper tubing with a large diameter
and proper spacing between turns but it was about equal to
a Hustler and considerably down from the top performer which
was top-loaded.

What wins the mobile shootouts is the longest possible straight
bottom section under the coil where the highest current occurs.
That maximum current occurs all up and down that straight bottom
section when a good top hat is added to the antenna. I once won
the shootout competition by putting all the loading (coil+top-hat)
at the top of the antenna using cheap stuff from my junk box.

If one wants to win a mobile shootout, one cannot afford to
install a helical coil at the maximum current section.

==========

Cec,

(1) A mobile antenna is NOT a 1/4-wave resonant, base-fed,
ground-mounted loaded vertical which behaves reasonably predictable.

(2) A mobile antenna is a relatively-isolated-from-ground, 1/2-wave
resonant, loaded, off-centre-fed vertical dipole which defies rational
analysis.

(3) It is impossible to separate the many different behaviour modes
and effects, differentiate between them and allocate relative
magnitudes. One has to be careful to control one's imagination when
describing effects.

I've never seen one near to, but I understand "screwdriver" type
mobile antennas are akin to long helicals specially at the lowest
operating frequency.

Reg.

All of the screwdrivers with which I am familiar use a
3-6 foot straight bottom section. The 2 foot max coil is
approximately in the center with a 3-6 foot whip. The coil
goes in and out of the 3-6 foot bottom section for tuning.

Do you subscribe to the theory that a one foot long coil
radiates approximately the same RF as a one foot long
piece of wire? With any reasonable diameter of coil, the
resistance in that one foot long coil will be greater
than the resistance in one foot of wire. For instance,
the circumference of a coil may be one meter while the
turn spacing may be one centimeter. What size wire do
you need to compensate for that 100/1 ratio?

Chas-- these are all the equivelant of a dipole bent in a circle for
more or less omni directional- and they perform about equallly.
One consideration is they often change SWR , in wet weather.,
but that is more a consideration for a mobile operator. M Squared
also makes a version , and see :

http://jonz.net/W3DHJ/6mhalo.html

and, : http://www.qsl.net/k4pwo/sloop.htm

if you want to give home brewing one a try. These are NOT gain
antennas, but on even medieocre openings on six, can work quite
a few folks. For more effective antennas, a yagi is recommended.
Have fun on six. Been there, and done that for over 40 years.
Jim NN7K

Best regards, Richard Harrison, KB5WZI

4181. Using 2 antennas as a repeater

Newsgroup: rec.radio.amateur.antenna
Date: 2005-03-25 23:08:18 UTC
From: Hal Rosser <hmrosser@bellsouth.net>
Message-ID: <WL01e.57616$6g7.20380@bignews1.bellsouth.net>
Source record: 80225

There was a question posted to another group about connecting to a distant antenna.
The post reminded me of another article (perhaps in QST) where someone who lived behind a mountain used 2 rhombic antennas as a "passive repeater" on uhf. He mounted both antennas at the summit of the mountain with one pointed to the repeater and the other pointed into the valley where he lived. As I recall, he was then able to communicate via the repeater.
This brings up other possibilities - like doing the same thing for inside-outside of a metal bldg.

4182. Re: physical 1/4, electrical 1/2 wavelength

Newsgroup: rec.radio.amateur.antenna
Date: 2005-03-25 23:21:27 UTC
From: John Smith <assemblywizard@gmail.com>
Message-ID: <d226e8$35k$1@domitilla.aioe.org>
Source record: 80226

Well, the "1/4 physical, 1/2 electrical" (double quarter as my friend refers to it) will just have remain as it is.
Its' advantage of being lighter and easier to handle, while presenting less of a wind load and "leverage" again the mast and mounting hardware allows me to raise it to a greater height than the full 1/2--NOT to mention the advantage of NO ground radials. With this advantage, its performance rivals the full 1/2. Weather I am daft or not--I will be using this antenna for an omnidirectional source.
Those seeking a backpacking antenna, an emergency portable antenna, or an antenna for operation in difficult and remote areas, or those seeking stealth (just hide it in a larger diameter PVC pipe and call it a flag pole!) would, most likely, find this design can be used to their advantage.

This posting sequence has been an enlightening experience though, and well worth the trouble. I have learned that most will wage a "religious war" if they think anyone is going to challenge the generally accepted ideas and methods.
If you insist on going on, you will run the gauntlet of nay sayers and be attacked. Guffaws and slurs against your mental stability will assualt you.
If one is looking to try something new--this is NOT the place to discuss it.
Perhaps another news group, where those who seek to intimidate and "out shout" true expermenters would be banned and refused posting would be a workable alternative and more conductive to attempts to break the mold.

Regards

'Corse, consider that there are certain constraints-- one being that
the antenna must be within a small distance from one end of the loop.
(for passive reflectors, at microwave, believe, they state 2-3 miles
(MAX)). and two, consider that at VHF, there is an effect called
"KNIFE EDGE REFRACTION" that tends to bend a signal over a hilltop
to a distant target on the other side of that ridge of hills!
But, for cell phones in a vehicle, those thru the glass antennas
on cars, with a whip on the outside , and what looks like a PAWN
BROKERS 3 ball symbol on the inside, do exactly what you describe
(or at least are susposed to)! as info, Jim NN7K

Hi Jim,
Yes, I've heard of knife-edge refraction, but the instance I was referring
to in the article had a real positive benefit. As I recall, the operator
went from <zero contact> to <satifactory contact> by hooking up 2 beams
back-to-back at the summit, with one beam pointing back at him - and the
other beam pointed to the otherwise unreachable distant repeater.
I wouldn't have thought something like that would work without some
signal amplification. But it does.

Hi C. George, Thanks for the interesting info. I certainly did not
know the 160m radios dated to the 40's. My memories of 1950's law
enforcement are "Highway Patrol" starring Broderick Crawford on the BW
TV. I remember watching him standing outside his police car and saying
"10-4" into the mike. Then, he would sometimes put the mike to his
ear, as if it were a speaker.
At the time I didn't wonder about the antenna on his car. I would
expect from your post it would be 43mhz. I don't remember if that show
was any good or not?

It certainly works Hal

I use to live in a half below ground block of flats that had a 1/4 wave for 2M way up on the roof. One day I experimented plugging the coax end into my field day 5 element positioned at the end of the hallway and used my handheld maybe 30ft away. Having the yagi connected vs not was in the vicinity of 12dB but this was a real rough measurement.

Recently I had cause to model a passive repeater on 400MHz. We had a situation with a base station positioned on a plateau but at maybe 1km away had a deep valley (railway cutting) that at the base of was (measured) at around -95dBm. We needed about -85 so we put up a back to back yagi at the valley edge and with it receiving an approx -10dBm signal the valley floor was now at around -80dBm at 200M away inside the cutting. Its actually pretty easy to model. Just find the pathloss of one link and add it to the other. Allow maybe 3dB loss for the passive coupling and there is your answer!

Cheers Bob VK2YQA

Nigel
I have little experience with dish antennas but I do know that to provide
the 'new' it is
one percent insparation and 99 percent persperation, so how about this
aproach:
Determine frequency of use.
Then draw a graph of frequency versus reactance change from a zero point
indicating resonance
of the prime frequency.
This curve is parabolic and would be an ideal starting point as there would
seem to be a connection
If one would move to far away from the point of resonance I would suggest
that the dish it's self
would rise in temperature as current starts to flow instead of a pure 'loss
less' reflective action.

well, yes, and no ! when still working for R.R., in the Sierras,
had such , on 2 GHz, dish's on a hillside to Colfax ,CA -- It worked-
sorta, was quite noisy, and had bad fade problems, even tho only
useing it to channel A-6 (highest freq was 32KHz for channel assignment)
and that was until coax link between the dishes leaked (water)!
A-6 is the lowest 6 channels in a multiplex system, and consider:
this was tied to a 300 channel (up to around 1.5 MHz) bandpass system!
(each channel = a voice channel, or up to 15 data channels (low speed))
To summerize, It can work, but most likely, not very effeciently.. Have
fun-- Jim NN7K

You are asking near impossibility, that is why there was no response.
QST had an Article on short, loaded beams, and W4RNL has written an
excellent Article on the same. Check those out.
Are you wanting to build or buy? This group, whom you don't think
much of, is mostly about design and building.

I haven't asked anything impossible or even tough, since I only gave a general bound on size, gave the rough band limits desired, and said we'd like gain and directivity.

As far as building goes, I've built about 20 times more than I've bought, so that's not an issue.

And where did I say I didn't think much of the group? I think the group is a wealth of ideas, creativity, knowledge and reason when they aren't bickering. I have learned a lot here reading threads, and also learned, to my regret, how much math has slipped from my grasp from lack of use over the years.

Chicago once dispatched their cars on a frequency of about 1700 kHz. Used to listen with a Wilcox-Gay receiver (made in Charlotte, Michigan) that had a knob used to switch from broadcast band to the MF police band. Long time ago!
I was of the opinion that the Chicago system was one way. Does anyone remember?
Some of the police HF frequencies were used on CW into at least the mid-60s. They were not allowed to use RTTY as it was thought to compete too much with The telephone company. I visited the main HF site for Ohio in the early 60s - the site was controlled from Columbus with a microwave link. The engineer liked to call it the longest IF in the world.

This posting sequence has been an enlightening experience though, and
well
worth the trouble. I have learned that most will wage a "religious
war" if
they think anyone is going to challenge the generally accepted ideas
and
methods.
If you insist on going on, you will run the gauntlet of nay sayers and
be
attacked. Guffaws and slurs against your mental stability will
assualt you.
If one is looking to try something new--this is NOT the place to
discuss it.
Perhaps another news group, where those who seek to intimidate and
"out
shout" true expermenters would be banned and refused posting would be
a
workable alternative and more conductive to attempts to break the
mold.
.....
I think I'm going to vomit....Are you related to Art? If not,
you should be....Whine, whine, whine.... You think you are the
first one to try that? I tried that using my helical mobile
antennas years ago...Big deal...BTW...I ended up preferring the
normal 1/4 wave config for a mobile antenna...Just in case thou
art interested...I also agree with one poster...The biggest change
will be with the current distribution...
They were making CB antenna *years* ago, using that "extended winding"
type of design...Many were a 5/8's wl winding. Sheesh....Get a grip.
Quit whining...Religious war? Slurs against your stability? Will be
soon, if you don't quit this retched "poor ole maligned me" whining.
You never saw me say anything about the antenna itself. Why? Cuz
being I have tried it, I know they can work. But like I said,
I ended up not using it as the normal 1/4 wl config worked better
on my car. Trust me...The idea has been tried long ago.
There is nothing wrong with posting something new here. Although
to others, it might not be new at all.
In fact, if you are *actually* interested in if it's viable,
this is probably the best place. You won't get suger coated
bullcrap here...
Now, if you are trying to push some funky device like say the EH
antenna, yep, you probably don't wanna be here...Go to a yahoo
forum where all have to register to join. That way you can control
all the posts, and make the outcome of your "discovery" come out

any way you want. Sheesh...

Hi Tom,

In article <4244b77d$0$3712$39cecf19@news.twtelecom.net>, you say...
>I haven't asked anything impossible or even tough, since I only gave a
>general bound on size, gave the rough band limits desired, and said we'd
>like gain and directivity.

Well... :-)

On a band that has a bandwidth of roughly 4% of
its center frequency, you're going to be REALLY
hard-pressed to get coverage of both phone and
CW on an antenna that is a little over 40% of
full size. So far, no manufacturer has been
able to come up with the antenna you describe.

Many years ago, Swan Antennas had a 2-element
40 meter beam that used half size elements.
As I recall, it used loading coils midway
through each element. I'm not very sure, but
I think the boom length was about 16 feet.
I think they got somewhere around 100 kHz
between 2:1 points. That wouldn't even cover
the entire phone band, and the elements are
longer than your design requirements.

So, yes, you are asking for something very tough,
if not impossible.

But, I wish you good luck in your quest! :-)

73,
Bob

And also from my original post

"o Boomlength 30 feet
o Element length 30 feet "

which is a whole lot more than 16 feet.

But you are probably correct. It's impossible.

Check out the Optibeam Moxon rectangle. I think its boom length is something like 20 feet. Also, the Moxon Antenna Project web site has a program for calculating the various dimensions.

4201. New Program RJELOOP4

Newsgroup: rec.radio.amateur.antenna
Date: 2005-03-26 06:19:40 UTC
From: Reg Edwards <g4fgq.regp@ZZZbtinternet.com>
Message-ID: <d22uts$1kt$1@titan.btinternet.com>
Source record: 80246

This program predicts approximate performance of general purpose, multiband, horizontal loop antennas of given perimeter of loop. It is not intended for precision predictions of operating data.

A loop is a continuous wire without loading coil or capacitor. It can be of any shape provided the area enclosed by the loop is not less than 2/3rds of that of a circle of the same perimeter, ie., it is not too irregular.

It is the sort of antenna which is forced on the amateur by the shape of his back garden and the pre-determined location of trees, poles, buildings or anything else from which an antenna wire can be suspended.

Analysis includes a high or low impedance feedline, a choke balun and an L-tuner. The antenna is most efficient when the perimeter is a whole number of wavelengths. It is least efficient when the perimeter is an odd-number of 1/2-wavelengths. But operation is not limited to being at, or near to, resonant frequencies.

Download in a few seconds program RJELOOP4 from website below and run immediately.

You can model this with EZNEC:

Get 2 Cushcraft 40M rotating dipoles and a boom to hold them. Tune the
dipoles separately to 7 MHz. Put them on the boom, observe operating
results, and adjust the driven element to your favorite 40M slot. The
elements interact, so the reflector may require adjustment as well, to keep
it around 7 MHZ when you adjust the driven element.

4204. Ladder line loss through brick

Newsgroup: rec.radio.amateur.antenna
Date: 2005-03-26 12:43:39 UTC
From: Joe McElvenney <ximac@btinternet.com>
Message-ID: <VA.000000c7.004d66b2@btinternet.com>
Source record: 80249

Hi,

My doublet is fed with 300-ohm ladder line passing through a 3/4" wide, 10" long hole in the outside wall, which itself is constructed of red house-brick. Is there any data available as to how much loss I should expect from this considering that the SWR will be quite high on most HF bands? A 'Google' search brings up a lot of data on wireless LAN (GHz) losses but nothing that is of much help to me.

The antenna is of indeterminate length (although longer than a half-wave on 3.5MHz) and is matched at the transmitter by a balanced line tuner.

Source record: 80250

No, FSK is not CW. Although others have provided a technical definition of FSK (Frequency Shift Keying), from a practical standpoint FSK is one of two methods that hams use to transmit in RTTY mode.

Unlike CW, where characters are constructed by sending combinations of short (dot) and long (dash) signals all on one transmit frequency, RTTY characters are sent by shifting your transmit frequency back and forth between a higher (mark) and lower (space) frequency. In most ham circumstances, those two frequencies are 170 cycles apart.

Hams use two popular techniques to create those 170-hertz shifted frequencies:

- FSK, in which the VFO of the transmitter "knows" to shift its frequency hi/lo in response to an input signal on the rear panel. FSK mode functions when the transceiver is in RTTY mode.

- AFSK, in which a computer, using software that controls its sound card, generates the correct tones and those tones are fed into the microphone input of the transceiver. AFSK mode functions when the transceiver is in SSB mode

SSB and CW are the modes you will want to use. The US SSB call frequency is 50.125, with the DX window below that. Some available propogation modes are troposcatter, F, E, aurora, auroral-E. Six is the band where almost all enhancements shop up occasionally. When the band is open, it's often wide open. Don't be discouraged if you don't hear anything for days or weeks. It's a lot like fishing. There are also seasons for some propogation types. You will soon see more E as we get into late spring.

And listen for beacons; sometimes the band is open, and no one notices for a while. Here are a couple links for beacons -

> K8UT

Larry you were doing good to you got to AFSK. When pure sine waves are fed into a SSB transciever audio, the output of the transmitter is the same as FSK. This is what is suspose to hapen when using the sound card.

AFSK is generated if the transmitter is in the AM or FM mode. This is used mainly on VHF and above on FM to use the digital modes such as rtty.

Tom is correct, and also remember : that for FM, transmissions are
USUALLY vertically polarized (I say that because ALL fm activity
for repeaters uses vertical whips, tho in an opening, anything works).
These loops are horizontally polarized). Dont expect much in the way of
F2, or TE, for about another 8-9 years (we are on a decline in the
sunspots), but Es is the bread and butter of the six meter operator,
and as Tom says, most activity is on CW, and SSB , tho I expect that
the new digital modes will start showing up more regularly.
That opens up another can of worms, as the CW segment of 6 meters
(50.000-50.100) ,unlike all other bands (except 2 meters), is
A-1 ONLY (at least in the U.S.)! This forces these new digital modes
up to around 50.26-.29 vacinity. Another frequency to note is 50.110
this is for the DX calling freq- read that as NON US-CANADA If you hear
someone there, is is a pretty safe bet that it is a foreign station.

As to what is being heard on six meters, try :
http://www.dxworld.com/50prop.html
A real time prop. logger for 6 meters
OH2BUA has similar, but mainly followed by Europeans. Six meters will
start opening eS on a regular basis probably by the middle of april
and peaking out in August. and there is also another 2-3 week peak
around the winter solstice, but 6 can open at ANY TIME !
And one of the charms of it iswhen it opens , even the low power
stations can work a lot. Normally, 6 activity on SSB doesn't get much
above 50 250 (unless its a real barnburner of an opening). A fun band
to operate. Jim NN7K

4213. Helical wound slim jim?

Newsgroup: rec.radio.amateur.antenna
Date: 2005-03-26 16:18:39 UTC
From: John Smith <assemblywizard@gmail.com>
Message-ID: <d2420u$r4l$1@domitilla.aioe.org>
Source record: 80258

Anyone ever done a helical wound "Slim Jim?" Since this is a 1/2 wave antenna with a 1/4 matching section (3/4 overall), helical winding of this form into a 3/8 overall height (approx. 12 ft. @ 28Mhz) might be possible. The extremely low angle of radiation (approx. 8 degrees) would make this vertical antenna desirable...

Regards

aunwin@insightbb.com wrote:
> If photons have no mass I do not see how they could become entangled!

Photons have no *rest* mass. When they are associated
with RF waves, they are traveling at the speed of light
and thus indeed do possess mass. Experiments have been
run on entangled photons. I'm about 2/3 of the way through
entanglement, by Amir D. Aczel. Einstein's work suggested
entanglement but he said it was "too spooky" to actually exist.

Quantum physics is indeed spooky. A single bucky ball, made
up of 60 carbon atoms, has been shown to interfere with
itself in double-slit experiments. It is certainly spooky
to see a single molecule of 60 carbon atoms behave like a
wave instead of like a particle.

> As for electrons don't they just re-orient instead of travelling?

Electrons are charged particles and move in the presence
of EM fields. Since they possess mass, they move relatively
slowly compared to the speed of light. Someone recently
posted the speed of electrons in a wire.

Hi John,

Rote learning comes through repetition:
The physical size in relation to wavelength dominates launch
characteristics, NOT electrical length.

As slim jims are generally applied to UHF/VHF use, line of sight
dominates both - that is why helically wound resistors (HT rubber
duckies) work as well as they do.

Hi John,

You will have found a very special population of scribblers at that
halcyon news group. That few who were untutored with the design of
millions of rubber duckies would be the only throng capable of hailing
true expermenters of the helical 1/2 wavelength antenna mold.

Drop us a note when you find the select. Stay away from their
kool-aid.

I heard that a 1/2 wave vertical has a Z of about 2000 ohms at the base.
Is this the Z between the base of the vertical and ground that RF at the
resonant frequency
'sees' ?

Doesn't the height that the vertical base is above ground affect this
2000 ohm valve?
Or does then metal car roof nullify any height above ground affects on
the Z?

I've noticed that measuring the return loss of a 1/4 vertical is very low.
But measuring the return loss of a 1/2 wave or 5/8 wave antenna is
higher.?????????????

Is remote tuning an option?

Thinking helically loaded elements with an adjustable piece of short
metal pipe around each element half, or a metal rod inside the turns .
Move the pipe(s) towards or away from the feedpoint/centre. Using string
of course!

Could also put an adjustable C across the feedpoint?

Cheers Bob VK2YQA

Yes, if the base is above ground, it will affect the impedance.
Consider that the feedpoint impedance of any vertical (any length, any
diameter) fed against a perfect ground plane in freespace will be
exactly half the impedance of the same vertical fed against a mirror
image of itself in freespace (in other words, a symmetrical dipole).
The closer the base is to being a ground plane, the less effect there
will be because of its height. How big is that car roof compared to a
wavelength of the frequency you're interested in? Since the impedance
of a halfwave fed against whatever counterpoise you have will depend a
lot on the diameter of the halfwave element, you'd probably better just
tune your matching network to get acceptable match to whatever you're
using to feed the antenna.

If there's no matching network between your "return loss measurer" and
the antenna feedpoint, I'd expect a better match for the quarter wave
than for the half wave, assuming an instrument calibrated for 50 ohms
(or even 75 ohms). A better match would be a higher return loss. Are
you interpreting the numbers correctly? What do you get when you put a
50 ohm load on your instrument? What do you get when you put a 1000 or
2000 ohm load on it?

Cheers,
Tom

==========

It is important to ask the right questions. The right questions are those to which there are answers and practical measurements can be made to confirm them.

For example, there is no answer to the question what is the impedance between the lower end of a half-wave dipole and ground when the lower end is at a height above ground.

It is impossible to make such a measurement directly because the impedance meter MUST be associated with a length of wire which reaches between the bottom end of the antenna and ground. This length of wire MUST form part of the antenna and the antenna length is then no longer a 1/2-wave dipole.

If the impedance meter is connected directly to the bottom of the antenna then the measurement is no longer with respect to ground but with respect to ground PLUS the impedance of that length of wire whatever impedance it may have.

I hope, but I doubt it, whether I have made myself clear.

To understand what is going on it is necessary to resort to theoretical arguments. Only the arguments are real - not the measurements.

Thre is a 1/2-wave dipole isolated in space. It doesn't matter whether it is horizontal or vertical. It is possible theoretically to calculate from its length, diameter and frequency its input impedance at one end.

But relative to what? To measure it is impossible. To where is the other side of the meter to be connected? Nevertheless we mustn't allow this stumbling block to get in our way. The theoretical, perhaps approximate, calculated value can be used in further calculations to answer real and very practical questions.

The input resistance of a half-wave vertical near to ground is 2 or 3 thousand ohms. It is uncertain because it depends on wire/conductor diameter and on the conductivity and permittivity of the soil. Because of its high value it is also sensitive to the antenna's environment, trees, etc.

When fed at its base, near to ground, its input resistance can be considered to be its radiation resistance. Because of its high value relative to the ground connection resistance, very high power efficiency can be expected.

Incidentally, half-wave or 5/8ths-wave verticals (not critical) have the lowest radiation angles and are therefore good DX antennas preferable to 1/2-wave horizontal dipoles at HF.

Mark is right. This is an ancient antenna. Anyone interested can
look up the article on normal-mode helical antennas in the
Antenna Engineering Handbook and get some references at the
end of the chapter for further study. Most of references date from the
'60s and '70s.

Line of sight is certainly what I had in mind. The purpose of shortening an antenna and making it easier to handle and less of a wind load, stronger, etc. would be to make it possible to elevate this antenna to greater heights and be able to withstand more demanding weather conditions.
Indeed, the 8 degree angle of radiation, which you state is ONLY factor of physical length, is what one would hope could be manipulated and brought into play--this low angle of radiation suggests itself to line of sight naturally.
If this antenna is light enough and disguised (painted gray as opposed to gleaming metal in sunlight) it might be possible to utilize very heavy fishline or weed-eater line to elevate this antenna to expanded heights using existing structures.
Since even a 20 meter version of this design would only fall in the 20+ ft length--respectable height would certainly be possible with these means--between two tall trees, placed at the top of tower, top of a tall mast, an existing guy line strung between telephone poles, etc.

The rubber duckie antenna is certainly useful for some situations, however, it is better if it stays on the walkie-talkie and we use another design for portable or base use.

Regards

Cecil,
FB on the thick Plexiglas! I was thinking along the lines of window pane thickness. I put a couple of 2 x 4 feet 1/8" Plexiglas panels on the back porch to keep the dog from clawing the screen out. She made very quick work of those :)

I went back to Home Depot and replaced them with Lexan, and nooo problem!

I have your page bookmarked, Cecil...I'll go there and take a look.

As I said before, Lexan is a trade name for polycarbonate. That's the stuff I curse at when trying to open a package that typically hangs on hooks in a store. Even using scissors, it's very tough to cut. A few year ago, when my son had an RC car, the bodies were made out of polycarbonate, and you painted them on the inside. Very indestructable in that applicaton.

The term entanglement, as used in particle physics, has nothing to do
with mass but rather a state or spin. Electrons are a bare charge
surrounded by a shield of photons. What we measure is the leakage that
gets through. Since light is affected by gravity, doesn't this show a
link between gravity and electromotive force?

BTW Cecil's body is made up of baryons.

Doc, you must not have understood what I sent. When a ssb transmitter is fed audio tones in to the mic input for digital modes such as rtty you are not using AFSK but FSK. It is AM or FM modes that feeding into the mic input that you generate AFSK.

YOu do not normally generate AFSK by feeding audio into the mic input of a SSB transmitter, you generate FSK. If a single audio tone is fed into a ssb transmitter you get a single frequency output. If it is changed in frequency you get another single frequency output. This is FSK even though you are using audio into the mic input.

If you feed a single tone into the mic of an AM transmitter , you get a carrier on the frequency and two sidebands (upper and lower) of the frequency of the tone. This is AFSK.

Frequency Shift Keying.
It was used allot when I was in the Navy (1950's) for Teletype Machines.
For all I know, it still is used.

I seem to remember "R-Y" as two letters I could type, and it would make the
Teletype Machine go from one extreme function to the opposite extreme
function, in the printer and machine and the code functions.
We used to use that as a way to check out if a machine was functioning
properly, as that would put it through all it's steps.
With age, I am wondering if I am right or wrong on it being R-Y.
Was it R-(?) ??
Best to all----

You are correct in the RY. Those two letters are the reverse of each other and should move the mechanical selectors from one extreme to the other . It is possible to have the receiver set to the wrong sideband or the demodulator reverse switch set to the wrong position and you will receive YR instead of RY. This makes for interesting problems for the new to rtty person. If a transmission starts off with a line or two of RYs and you are receiving YRs, when the main body starts up you will receive jumbled characters.

Altho , this is with the old 5 level code. For ASCII, there is no such
test, tho the closest you can get is the " J * " characters (J, then
upper case 8) as explained by an old boss and teletype mechanic.
and to compound it, the ASCII characters can use 1, or 2 stop bits at
the end of the characters! As info, Jim NN7K

Hi John,

Given this opprobrium, what makes its cousin for 20M more suitable?
[20M is not noted for being line-of-sight either.] The principle
annoyance to erecting antennas is in matching them, beyond that, any
radiator from 0.1 to 0.625 wavelengths pretty much has the same gain
in the same direction. The difference being that some are harder to
interface to a transmitter than others.

Hi Jim,

Also 1ï¿½ stop bits (unless I'm confusing this with RS-232).

When I was in San Diego for Instructor Training, one of my Radioman buddies told me how their final was given in the form of a box of RTTY parts that they had to assemble into a complete working machine. He also suggested that a wandering ET (my rating) would, on occasion (and hidden from view), donate extra parts to random boxes.

No doubt, the endowed RM striker would mutter some other meaning for FSK.

This is pretty much what I have run into from hands on experience, when a half wave is elevated above ground a 50 to 800 ohm stepup autotransformer constructed on a toroid usually is sufficient to get the SWR to a resonable level, infrequently a 1600 ohm tap works better (sometimes a match is had with a 4:1 balun, go figure.)
Anyway, I find impedance can be greatly affected by relatively small changes in antenna height...

If you meant that you would be putting up a vertical beam along with a
horizontal, I would recommend against the vertical as a waste of money.
There is little useful DX on 6M FM as a percentage, especially when
you consider contests, WAS, WAC, etc. When the band is open I can
almost guarantee that you will not switch to FM.

Mark is right. This is an ancient antenna. Anyone interested can
look up the article on normal-mode helical antennas in the
Antenna Engineering Handbook and get some references at the
end of the chapter for further study. Most of references date from the

'60s and '70s.

Of course it is. It often amuses me how often stuff is
"reinvented". Heck, I've even done it myself by accident...
But I never had any thoughts of filing a patent, or
whatever...I never had any delusions that surely no one
else in the world had thought of it, and it ended up as such.
I think people forget just how much antenna
experimentation has already been done. There was loads
of experimentation done from the 30's thru the 50's,
covering nearly everything imaginable. Ole John calls
me a nut, but if I hear someone say, "they all think
all is known about antennas" one more time, I'm gonna
puke. He and Art sound like the same whiny broke record.
Almost exactly to the word. Of course, no one here thinks
all is known about antennas. But I can assure you that
most all the theory has been pretty much etched in stone
for quite a few years. No one is going to come up with some
new gadjit that is going to break all the rules. Just
ain't gonna happen. Sure, minor touch ups of theory will
surely occur, but nothing major is going to be changed,
or it would have by now. It's comparible to the field of
aeronautics/aircraft,etc... People will continue to design
new aircraft, but no one is going to design something that
breaks all the rules. I've got a large walk in closet full of
QST's going back to the middle 30's. Thumbing through a few
of those 30's thru 50's issues might surprise some as to
how much was known even at that time. Nothing major as far
as theory as changed since that time, and that was a half
century ago. These days, if someone tries something that is
truly new, you can bet it will be pretty "out there". But
it won't break any rules of theory. It will just be a new
method of applying it. Unfortunately for John, what he is
doing is old news...But at least it's not something silly..
It is a viable antenna. And thus, not to say it's not worth
messing with...Everything I use is old news...Some of the
old news, will always be the best news...IE: no one is going
to be able to improve much on the efficiency of a simple
coax fed dipole on HF...MK

Surely this is not correct. There is no conventional way of
doing RTTY on AM or FM.

The distinction between FSK and AFSK is that the former
operates directly on the transmitter's frequency-determining
oscillator, while the latter works first through the audio
stages of an SSB rig to achieve the same on-the-air signals.

A friend asked me this question and he is not on the NG's, can someone here advise him.
His e-mail is tomkf8dx@att.net
or I will relay any responses that are posted here. - Thanks

"My question is the proper way to feed a 3 element end fire array.
What I have now is 3 dipoles 122 ft. total length. (61ft. per side) fed with 450 0hm ladderline, and spaced at 121 ft separation. I'm using 0.975 for velocity factor. the 450 ohm ladderline is NOT transposed. I'm feeding the array at the center dipole. What I need to know is , is this correct or should I transpose at out side dipoles, the feed line. The whole array is 242 ft. long. And is up at 85 ft. Nobody seems to know if I should change feed line or not. If you could help I'd very much appreciate."
Thanks es 73's Tom Weller KF8DX tomkf8dx@att.net

Well, maybe I was half-right. It appears that years ago,
AFSK did mean exactly what Ralph described with both AM and FM.

Today, AFSK has come to mean the use of audio tones to shift
the carrier frequency.

Sorry, and thanks for the opportunity to learn something
about changing customs!

73,

Chuck

Terman (Radio Engineer's Handbook, p 846) shows a chart for the radiation resistance and reactance ranges for five, guyed MW broadcast towers, as measured against a good radial ground system--an ohm or two above true earth. For electrically 1/2-wave radiators, R ranged from 300 ohms to 450 ohms and Z ranged from about -100 ohms to -350 ohms.

Check for the works by the late Dr. Branko Popovic,
who was a consultant to European broadcasters
on tall (> 1/4 wave length) vertical antenna array design.

He was my PhD research advisor at Virginia Tech
in 1968 and 1969. He was on an exchange plan
from Belgrade. I was his first PhD candidate.
He worked from physical reality on antennas
and was an inspiration to me.

Cheers,

Ron McConnell

4259. Narrow lobe of a yagi

Newsgroup: rec.radio.amateur.antenna
Date: 2005-03-27 16:20:58 UTC
From: "aunwin@insightbb.com"
Message-ID: <K3B1e.8558$NW5.7100@attbi_s02>
Source record: 80202

As gain increases with a yagi design the forward
lobe narrows . With high gain yagi's the lobe
becomes so narrow it is deemed to be a hinderence
instead of an advantage. To overcome this perceived
problem one has to know what causes it.
So to the gurus of this group, what actualy creates
the narrowing of the forward lobes ?
End effects perhaps!
Regards
Art

Huh, I didn't know this...for several decades now I've thought it was
an advantage.

For example my EME friends and I have always believed that focusing
the available transmit power on the moon on transmit and rejecting
stellar background noise on receive was desirable. How did we go so
wrong?

==========

As I said, 1/2-wave antenna input impedance is a function of conductor diameter. It is not a relatively fixed value (around 36 ohms) as is a 1/4-wave vertical.

Impedance decreases as diameter increases. Or as the ratio of height/diameter decreases.

Terman's LF and MF towers (not wires) have extrordinary thick conductors (probably latttice masts) compared with a low antenna height in terms of wavelengths. Hence the low input impedances in his examples.

If I remember correctly, Terman makes no reference to height/diameter ratio and is therefore misleading by using tower antennas as typical examples. He tells only half the story. Terman should not always be used as the Bible.

EZNEC can be used to estimate input impedances of the more common 1/2-wave wire antennas at HF when very near to ground. Which is what amateurs are interested in. They usually fall in the range 1500 to 3500 ohms.

At VHF and UHF with short, fat, thick rods for conductors, (similar in proportion to LF lattice towers) input impedances can fall to several hundred ohms or smaller.

Input impedance values of isolated dipoles are theoretically calculable but are impossible to measure. Nevertheless, calculated values are very useful in antenna system design. Couldn't do without them!

Maths takes precedence over measurements. Without maths, experimenters flounder about in the dark.

All is known about antennas isn't it?

It doesn't with my antenna where the lobe gets larger
as radiation is deflected to the forward direction.
Obviously with a yagi cancellation is occuring as well as addition.

>
>>With high gain yagi's the lobe

You are not alone as I thought it meant quieter contacts but it is said
(ARRL publication) that it then becomes more difficult to aim, ala the
rombic.
That's why I see my antenna's flattening of the main lobe without loss in
beam
width an advantage.

>
> For example my EME friends and I have always believed that focusing
> the available transmit power on the moon on transmit and rejecting

But back to the question.

Do you know what creates the narrowing of the main lobe ?
It only takes one diffinitive post from a real guru to explain and then
the others will follow. Until the real guru comes forward with an

explanation
all others will procrastinate and avoid the question without giving
a hint that they do not know and are awaiting the explanation from a real
guru.

If you actually know Wes then jump in so others may follow.

aunwin@insightbb.com <aunwin@insightbb.com@insightbb.com> wrote:

>It doesn't with my antenna where the lobe gets larger
>as radiation is deflected to the forward direction.

There is a harsh limit, imposed by physics, as to how much gain that approach can give you.

If all of the energy from one hemisphere is redirected into the other hemisphere, and if the forward-direction pattern shape does not change (the forward lobe is not narrowed), then you have a forward gain of 3 dB (2:1 power ratio increase). You *cannot* have more, as this would require that the antenna be radiating more power than it receives from its input.

A Moxon antenna is, to a first approximation, a pretty good example of this approach - it has very little energy in the rear hemisphere, and a broad forward lobe. There are various two-driven-element array designs which achieve a similar pattern and result.

> Obviously with a yagi cancellation is occuring as well as addition.

You are trying to draw a distinction between "deflection" and "cancellation" which I believe is invalid. Both are simply ways of describing the result of the "sum of vectors" effects of having energy from multiple radiators (driven or passive) combining in different phases at different locations. Same math, two different words.

>Do you know what creates the narrowing of the main lobe ?

Conservation of energy *requires* that the main lobe be narrowed, if you wish to achieve more gain than you can get by simply redistibuting the rear-ward energy in the forward direction.

A super-high-gain antenna *cannot* have a wide, uniform beam-width in both azimuth and elevation.

As usual for your postings, Art, it's impossible to tell whether your claims for your antenna are plausible, because you refuse to disclose *anything* (either the invention, or the results you claim) in any halfway-tanglible form (e.g. models, specific numbers, etc.).

Until you do, I really think it would be to everyone's relief if you'd follow through with your recent statement that you were going to stop posting. You're achieving no good result for yourself by contining as you are.

>
>Can anyone tell me how a thread disappears? Can it be deleted? By just anyone?

There's no universal mechanism for a "thread". It depends on your
news server and your newsreader.

Threads are often based on headers placed in the newsgroup articles...
when one posts a followup, the newsreader usually adds a "references:"
header which gives the article-ID of whatever message you're posting a
followup to. Newsreader programs, or Web-based newsreading services
can use these "references:" headers to deduce the linear or tree
structure of a thread of articles.

Some newsreaders don't use this information, and try to deduce the
thread structure by looking at the 'Subject' headers.

In either case, there's no standard for how a system maintains a 'list
of active threads', and there is no centralized registry. Each system
which stores and processes USENET news (Giganews, Supernews, Google,
and numerous smaller servers) has the ability to maintain its own
thread database, makes its own decisions about how such databases are
constructed, and makes its own decision about how long to store the
thread information and the underlying articles themselves.

Hi Art,

Because straightforward, simple answers seem to baffle you so
outright. See? Each and every post offers what is YOUR
responsibility to discuss, and by your choice you litter the landscape
with thrashing over style instead of content:

>Your response is pure rubbish

Let's call it entangled correspondence. Really, Art, you need to go
back to your disclaimers with each posting so we can tell when you
aren't serious.

>Why not wait for the real guru to post so you can float in on his or her's
>coatails ?

-Whew!- And here I thought you had reserved your venom of "guru" for
me alone. Thanx, that makes me feel so much better that you have
elevated me above that ill-bred population you so love to spit on.

>others will see you as possibly knoweledgable but not understood by the
>lesser educated.

Well, let's test that by returning to the topic and see which side you
occupy:

Now, do you dispute that sinus pressure DOES NOT create narrowing of
frontal lobes? Even the lesser educated know this for a fact, Art.
Are you suggesting that perceived problems of yagis cannot be cured
with an omni with amplification? Something tells me you already had
an answer for that hidden up your sleeve (without data of course but
perfectly proven with chords and tangents).

I await your Euclidean gymnastics. ;-)

Terman's chart, which I scanned and emailed to you, shows a 1/4-wave vertical with an ~R of 31 ohms to 48 ohms, and ~j of -15 ohms to -40 ohms for the five MW towers. This range actually is about the same by % change as shown for the 1/2-wave radiator (~R of 300 ohms to 450 ohms, ~j of -100 ohms to -350 ohms).

> Maths takes precedence over measurements. Without maths,

Check out the scans of the antenna here:

http://home.earthlink.net/~rmowery28146/data/

It is from the 1981 Handbook. It is slightly larger than specified but may
be usable. The Files are about 1 and 2 meg in size.

> (the forward lobe is not narrowed), then you have a forward gain of 3
> dB (2:1 power ratio increase). You *cannot* have more, as this would
> require that the antenna be radiating more power than it receives from
> its input.

Absolutely incorrect. If I place the air of two balloons ,which reflect the
figure
eight,into one single balloon and where the laws of partial pressures do not
intervene
then you will have a balloon that is round and not elongated as the antenna
books
would have you suggest. "Gain" is a term used to to quantify a small
portion of the
energy contained in the mythical ball of energy. Since the collection of
energy comes
from different directions and phases the energy collection is layered
depending on
the influence of the earth. Thus the layers of radiation are distorted
where one layer
can be squeezed outwards further than other layers, thus the terminology
of "gain"
If you are going to interelate the terms of "gain" and "power" then you must
define
the parameters used to allow that.

>
> A Moxon antenna is, to a first approximation, a pretty good example of
> this approach - it has very little energy in the rear hemisphere, and

> designs which achieve a similar pattern and result.

And the resulting "gain" is ....what?
I have difficulty in getting beyond 16 dbi as any additional energy from the
rear
has very little effect on the diameter of the frontal lobe.

>
>> Obviously with a yagi cancellation is occuring as well as addition.
>

> "cancellation" which I believe is invalid. Both are simply ways of
> describing the result of the "sum of vectors" effects of having energy
> from multiple radiators (driven or passive) combining in different
> phases at different locations. Same math, two different words.

Yes I agree because of conservation laws e.t.c . When cancellation occurs
then energy creats energy in another direction similar to pulling steel
apart in tension
(or using compression) the steel becomes narrower before severing occurrs.
This thinning or "waisting" is created by the additional forces created at
90 degrees
to the tensile forces and where the break actually occurrs at 45 degrees
and not at right angles.
>
>>Do you know what creates the narrowing of the main lobe ?

>
> Conservation of energy *requires* that the main lobe be narrowed, if

> the rear-ward energy in the forward direction.

This is what you alluded to before and it is still incorrect
What "requires" what ? And how is this conclusion generating
an elongated lobe?

>
> A super-high-gain antenna *cannot* have a wide, uniform beam-width in
> both azimuth and elevation.

Don't know how you can say that unless somehow you generated a single lobe.
Now that would be interesting

>

My antenna is somewhat related thus my interest in what creates an elongated
lobe
which is formed using Yagi principles.
The question however, is specifically related to Yagi's
and its narrowed lobes.
Do you know what it is that creats an elongated lobe

on a high gain yagi i.e not totally round.?
Nothing more, nothing less.
Regards
Art

A good analogy that needs no math to understand is that of squeezing an inflated balloon from its normally spherical shape into whatever shape is more appropriate for the application. There is a given volume of air in that balloon. If you want the surface of the balloon to extend further from the origin of its original sphere, the new shape must be narrower in one or more planes than the original shape.

The shape changes can come from squeezing the balloon (pattern) horizontally, vertically, or in combination -- which, in antenna hardware is accomplished by an appropriate array of, and feed system for, its radiating elements.

"Freebanding" is quite common these days.
However, from my observations, you are much more likely to find a ham on CB having fun and rabble-rousing with the truckers and "country folk" than a trucker on the 10 meter band.
Be it as it is... truckers probably well outnumber hams in the US... and CERTAINLY provide a much more valuable service.

The narrowing of the forward lobes is
caused by constructive interference
during superposition of EM waves.

>So to the gurus of this group, what actualy creates
>the narrowing of the forward lobes ?
>End effects perhaps!

My tuppence worth

It is a fundamental energy conservation effect.

There is an invariant A * Omega , where A is the capture area of the
antenna, proportional to gain and Omega is the solid angle of the lobe.

So as A goes up, Omega must come down.

One way to reduce the effect is to use a number of vertically stacked
low gain yagis. The lobe becomes narrow in the vertical plane , but
remains broad in the horizontal plane. This is fairly common technique
for VHF/UHF contesters, where a narrow horizontal beam can cause missed
contacts

Richard.
No one has come up with a explanation BUT there are real gurus out there,
It's just that those who qualify as gurus have just thinned out a bit.
The question still pertains to Yagis and the narrowing of lobes
You have posted twice now and added nothing that relates to a possible
answer.
Tho there are many who perceive themselves as experts and then consistently
show
what they really are. I can think of one or two who can really address this
question
with a logical answer. Cecil, Roy and a couple of others qualify and have
yet to respond
You have disqualified yourself based on your responses, so like myself you
will have to wait to learn. Yagi's have been studied in depth and for many
years by many
tho apparently not by you or others that have replied so far.
Place your bets on who is the real guru of this group that comes forward
to explain with logic and to the point You Richard, can read your old QST's
in a hurry
and surely find the answer to get back into the ratings as I don't think
that new
knoweledge is around the bend, just a small manipulation of "old" knoweledge
will
surely suffice. Think "end effect" and "none- resistive residuals" along
coupled radiating
elements for starters.If that draws a blank then assuredly you wear no
clothes

See

http://www.somis.org/bbat.html

But it still requires a balun. If you wish to use no balun then you'll
need to build a link type tuner.

Right..... so what creats it, this "squeezing" that you talk about and from
where
does this "squeezing force come from in an "appropiate"array?
That's what I was asking not a discussion of what the
Yagi array produces. Why does the lobe narrow?

Maxwell and Einstein assumed the locality principle which
has now been disproved by quantum physics. Anyone want to
predict the effect of non-locality on Maxwell's equations?

Yes Cecil I can go along with that otherwise the resultant volume would be spherical.
What is the scenario that encapsulates this "constructive interference" event? Is it residual reactance where its underpinning reside?

Yes they do provide a valuable service, however, that does not give them the right to disobey the law - be it the FCC's laws or even speed laws. What you seem to be implying is that their service gives them carte blanch to do as they please.

Maybe Hams do go on CB bands, so what! As long as it is with Type accepted equipment, meaning a "legal" CB set, there is nothing wrong with that picture. IF they are using HAM gear to talk out of Ham bands, then it too is illegal. To go into the ham bands with out a license is also illegal.

There's no other way to cut it - you either operate within the law or contrary to it. IF contrary, then you have no claim in your defense, as they do not accept the "ignorance" excuse. The law is the law until someone decides to change it.

With all the disobedience in this country, no wonder it is going to hell in a hand basket.

Are the threads still available on Google? If so, you can
add that additional post through Google and it will show up
here.

Threads can be canceled by the poster. Graphics postings
to text-only newsgroups are automatically deleted. Obscene
material is often deleted. Server problems can cause loss of
threads. On some usenet news servers, there is an option to allow
a posting to expire after N days. For instance, the announcement
of a hamfest should expire after the hamfest is over.

My post was simply a list of facts as they appear to me. The use of communications to assist in the delivery of medicine, food, clothing, building materials, etc. is of more importance than the use of airways for recreation.
Since most would accept that the law of "...the greatest good for the greatest number..." would apply, if push came to shove--the truckers would probably end up with the frequencies in question...

4295. Re: what does fsk mode mean

Newsgroup: rec.radio.amateur.antenna
Date: 2005-03-27 20:23:54 UTC
From: chuck <chuck@nospam.net>
Message-ID: <4247166b_1@newsfeed.slurp.net>
Source record: 80140

Well, I have a "latency" problem between typing out postings
and engaging my brain; hence the nonsense in my previous two
posts.

Here's what I now think, and I agree with Ralph. AFSK refers
to a type of modulating signal that switches between two
audio frequencies. In other words, the audio frequency is
shifted to key the transmitter. It doesn't mean (as I
suggested earlier) that audio is used to shift the carrier
frequency, although that is the result when you modulate an
SSB transmitter with AFSK tones.

When applied to an AM or FM transmitter, the notion of AFSK
modulation still makes sense. It produces something other
than FSK, of course. But with the proper detection to
recover the modulating tones, there is no reason you
couldn't use AFSK with AM or FM transmitters for RTTY. And
indeed, AFSK is used this way on FM and AM rigs (as someone
has pointed out), although not usually for RTTY.

So the semantics seems to hinge on whether FSK and AFSK
refer to the resulting RF waveform, or to the modulating
signal. The latter notion is broader, and is what I now
understand Ralph was saying.

Thanks, Ralph.

Chuck

There is a nation wide radio service for truckers and what the truckers are doing when they go to Radio Amateur frequencies is a crime. These frequencies are used for many different things including emergency communications in disasters, the HFers simply do not belong there!

Regardless of your poorly reasoned opine.

Darn - I thought it was pure magic.
Now we hear all about induced currents and interference patterns cancelling in the rearward and the sides, but constructively interferring in the forward direction. All in an attempt to become the chosen guru of the original poster.
If nominated, I will not run - if elected - I will not serve.

Sure. The simplest way to state it is "the total amount of power
delivered by the antenna, summed over all of the possible angles of
radiation, must equal the total amount of power radiated by the
antenna."

>>

Jeez, Art, do you have any idea of just how thoroughly your response
qualifies as "Authentic frontier gibberish" (as a Mel Brooks character
once said)?

I'm sorry, guy, but I believe that you are trying to stretch analogies
far beyond the point where they actually apply to the physical
phenomena we're discussing. Your concept of "layers of radiation" (as
applied to the gain pattern of an antenna) simply doesn't add up.

>If you are going to interelate the terms of "gain" and "power" then you must
>define
>the parameters used to allow that.

OK, let's do just that.

"Power" is very well defined - it's the rate at which energy is delivered. Pick your units for energy and time as you choose. It's conventional to use watts for power, joules for energy and seconds for time. One watt, equals a rate of energy delivery of one joule per second.

"Gain" is a ratio. In discussions dealing with antennas, the gain describes the ratio between the amount of power delivered by a given antenna in a given direction, to the amount of power delivered in that same direction by a "reference" antenna (a dipole in the case of a dBd gain number, and an "isotropic" antenna in the case of a dBi gain number). The gain figures in dB are logarithmic.

Those are the definitions everyone uses, I believe.

If you, personally, are using different definitions than these, then our discussion (you vs. everyone else) should probably stop right here.

Here's my rationale behind the statement I made about the limitations of your approach:

- An isotropic antenna has a gain of 0 dBi, by definition.

- If you "cut off" the entire rear side of an isotropic antenna's pattern (so that it radiates no power backwards), and precisely overlay this power (energy flow) onto the forward half, you'll end up with a "half-isospheric" antenna. It's radiating exactly the same amount of power, but over only half as much target area. The power (energy flow) towards each point in that targeted hemisphere will be exactly twice as much as in the isotropic antenna.

This antenna has a gain of 3 dBi plus a hair.

It cannot have *more* gain in any direction (more power into a sub-portion of the hemisphere) unless it has *less* gain in another portion of that hemisphere... in other words, unless is starts exhibiting some form of lobing/nulling.

If it *could*, it would be trivial to demonstrate that the antenna was delivering more power (more energy over time) into its loads, than it was accepting from its transmitter.

The same line of logic applies even if you start with a dipole. If you begin with a dipole, and then magically "deflect" all of the power from the rear towards the front and overlay the patterns exactly, you'll exactly double the power in each forward-lying half of the sphere, and create a gain of 3 dB over the dipole. In order to have *more* forward gain in any direction in the forward direction, you must necessarily have *less* in another, and this either narrows the

pattern in the forward direction or creates partial or complete nulls.

To claim otherwise, is to claim an antenna which can be shown to deliver more power than it accepts as input... in other words, one which violates the conservation of energy.

The same basic rule applies for any situation in which you take a bidirectional antenna (one which has a symmetrical forward-and-backward gain pattern) and then "deflect" all of the rearward energy into a forward direction. This will gain you at most 3 dB over the basic gain pattern of the antenna you started with. Any further maximum forward gain, over the antenna you were starting with, can *only* be achieved by decreasing the gain somewhere in the pattern (narrowing or weakening the main lobe or one of the sidelobes).

>> A Moxon antenna is, to a first approximation, a pretty good example of
>> this approach - it has very little energy in the rear hemisphere, and
>> a broad forward lobe. There are various two-driven-element array
>> designs which achieve a similar pattern and result.
>
>And the resulting "gain" is ....what?

According to Cebik's web site, a 2-meter Moxon shows a maximum forward gain of about 10.7 dBi, or a bit more than 8 dB over a dipole. One could gain at most 3 dB due to the forward "deflection" of rear-hemisphere energy, and hence the remaining 5 dB or so of gain over a dipole must come from a narrowing of the antenna's pattern in either azimuth or elevation or both.

>Yes I agree because of conservation laws e.t.c . When cancellation occurs
>then energy creats energy in another direction similar to pulling steel
>apart in tension
>(or using compression) the steel becomes narrower before severing occurrs.
>This thinning or "waisting" is created by the additional forces created at
>90 degrees
>to the tensile forces and where the break actually occurrs at 45 degrees
>and not at right angles.

Art, I think your analogies between radiation patterns, balloons, stretching metal, etc. are leading you astray more than they are helping you.

>> Conservation of energy *requires* that the main lobe be narrowed, if
>> you wish to achieve more gain than you can get by simply redistibuting
>> the rear-ward energy in the forward direction.
>
>This is what you alluded to before and it is still incorrect
>What "requires" what ? And how is this conclusion generating
>an elongated lobe?

>> A super-high-gain antenna *cannot* have a wide, uniform beam-width in
>> both azimuth and elevation.
>

>Don't know how you can say that

I say that because the opposite case would contradict the law of conservation of energy.

If you have an antenna which puts all of its power, uniformly, into a forward beam which covers only 1/10 of the sphere, then that forward beam will carry 10 times as much power per angle, for a gain of 10 dBi.

If you squeeze the beam down in size so that it covers only 1/100 of the sphere, it will carry 100 times as much power per angle, for a gain of 20 dB.

You can't have a broad forward lobe (say, one which covers a full 1/10 of the sphere), and achieve a high gain of 20 dB (100 times as much power per angle) without violating the law of conservation of energy.

THAT is the fundamental limit I'm talking about, Art.

>> As usual for your postings, Art, it's impossible to tell whether your
>> claims for your antenna are plausible, because you refuse to disclose
>> *anything* (either the invention, or the results you claim) in any
>> halfway-tanglible form (e.g. models, specific numbers, etc.).
>
>
>My antenna is somewhat related

You DID IT AGAIN, Art. You said "is somewhat related", you didn't say related to *what*, you didn't give any details whatsoever.

>The question however, is specifically related to Yagi's
>and its narrowed lobes.
> Do you know what it is that creats an elongated lobe
>on a high gain yagi i.e not totally round.?
>Nothing more, nothing less.

You're acting as though the lobe were a physical object, and that something is "putting pressure" on it to squeeze it out of shape like a physical balloon.

That is a FALSE ANALOGY, Art. It's meaningless.

The "shape" of the lobe is simply a way of plotting numbers on a graph. It depends on the scaling of the graph, and it's a *relative* scale. A dipole's lobes may look perfectly round on one sort of graph, elliptical on another, and lumpy on a third, depending on whether the plot's axes are logarithmic, linear, or somewhere in between the two.

Fundamentally, the reason that the shape of the lobe (on a conventional plot) changes from somewhat-circular to more-eliptical is due to the fact that the antenna is sending more of its power in a favored direction (to achieve gain), at the expense of sending less in

other directions. Period.

The *mechanism* by which this is done, in a Yagi (or an actively-
driven set of phased radiators), is simply one of dividing up the
power being radiated so that it's radiated (or re-radiated) from
multiple points, in different spatial and phase relationships, so that
the resulting waves cancel out in certain directions and reinforce in
others.

If you really want to know the details, I suggest that you dig up and
read the original papers by Uda and Yagi.
>> Until you do, I really think it would be to everyone's relief if you'd
>> follow through with your recent statement that you were going to stop
>> posting. You're achieving no good result for yourself by contining as
>> you are.

>I have not posted as you have inferred. The question is about Yagi design

It all seems to come down to the same thing with you, Art.

I suppose I should just killfile you and completely ignore your
postings. I'm sorry, I've tried my best to steer you in directions
that I think will actually help your efforts, but it seems quite futile.

Actually, the use of bandwidth for recreational purposes provides NO real
revenue for local, state or federal government. With the outstanding costs
of government--it would be most logical to switch much of this wasted
bandwidth over to private enterprise where real tax revenue could be
recovered...
Recreational communications are probably much better suited to the internet,
again, where the greatest numbers receive the greatest benefit.
My "faulty" logic is indicating to me that this is the direction things will
go, when finally these issues are put under a microscope and examined.
Since my crystal ball is cloudy at the present time--I will await the future
for confirmation...

Narrowing is the natural result of the vector addition of the separate EM waves radiated from the individual sources comprising the Yagi (or any other kind of directional array).

I doubt it..... just because a "group" wants something, doesn't mean they'll get it. Your group may be in numbers due to the job they do, but not in other avenues as well - nor does it give them the right to break laws. Again, the law IS the law - until someone changes it. Given there are many truckers who are also VALID hams, its doubtful they would vote in your favor. They don't break the law, they got their license unlike others who are too lazy to get up off their ass and make the effort to learn what little it takes to get a license. A few years ago, it was tough for those who had no inclination to learn. Many years ago, you even had to draw schematics and even before that - BUILD a circuit. Given the poor poor pitiful me act which someone had enacted for stupidity's sake, now the tests are made so it's almost impossible to fail. Try studying, get your license, then use H.F. to your hearts content. The use of communications for what you mention, can be left with the CB band, it works just as well right there. If you guys would quit running power, echo boxes, etc to drown each other out and splatter all 40 channels, maybe more could talk and get the communication through. A clean signal gets through every bit as good or better than one filled with garbage. Try it sometime. The only one's you'll be competing with are your buds who still talk with the garbage. Too bad the FCC hasn't thought of setting up shop at the Weigh Stations. They could bust the truckers for illegal radios while the cops are busting them for bad mechanical problems, poor log books and so on. The FCC "has" busted a few truckers, just not enough. NO JOB - I don't care what you do - gives you the right to break the law or think you're special. I know a trucking company who just lost most of their hauls due to the oil prices. Now the loads go by Train. So DO NOT THINK - you are so on top of the world. It could come crashing down.

>Right..... so what creats it, this "squeezing" that you talk about and from
>where
>does this "squeezing force come from in an "appropiate"array?

There is no "force" in the usual sense of pressure on a physical
balloon. That's because the "balloon" is not an object. It's simply
a mathematical abstraction - a drawing of lines of equal RF power
levels on a graph having a certain set of axes.

To think that there's a specific 'force' squeezing the 'balloon', is
somewhat like trying to travel from east to west by pulling yourself
along the lines of longitude. Hey, the lines are there on the globe,
they're there on the map, why can't I just walk along the lines?

There's nothing "pushing" on the "boundaries" of the lobe, because
there is no lobe in the physical sense. It's not a separate and
distinct object.

To understand why there's a change in the shape that we visualize (and
that's all that the lobe shape is - a selective visualization), we
have to step down to the underlying phenomenon and see what's changing.

Because the conventional "lobe shape" is simply the result of plotting
the strength of the RF energy coming from the antenna, the answer is
simple. The lobe's shape is changing, because the amount of RF energy
being transmitted in the different directions is changing...

... and *that* happens because the phase-and-location details of the
various radiators (and re-radiators) in the antenna system are being
altered.

Different radiator and re-radiator locations, intensities, and phases...

... cause different "sum of vectors" results ...

... which changes the strength of the RF received ...

... which, when we walk around and try to locate the points
having equal RF field strength, means that we walk along
different paths ...

... which means that we draw the lines on the map in
different places ...

... which means that the "lobes" now have a different
shape.

>ideas and thanks in advance.

You'll need some form of inductively coupled ("link-coupled") tuner to
do this. The most popular of these at the moment seems to be the
"Z-match" - it has good although not perfect current balance on the
outputs.

Most of the Z-match designs I've seen can be implemented with two
variable capacitors, and one fixed inductor. There's a "two coil"
Z-match but I gather that it doesn't really have advantages over the
one-coil variety. The coils can be either air-wound, or wound on a
powdered-metal toroid.

>... any radiator from 0.1 to 0.625 wavelengths pretty much
> has the same gain in the same direction.

This will be news to the FCC and AM broadcast stations, all of whom understand that the ground wave from radiators of the heights you mention above varies WIDELY, as demonstrated by empirical measurements going back some 70 years.

For example, a 0.1 lambda radiator has about 54% of the groundwave field as one of 0.625 wavelength, assuming a very good ground system for each (1 ohm or so).

A matched radiator of 0.1 lambda height would need about 3-1/2X as much input power as a 0.625 lambda matched radiator in order to generate the same ground wave field strength over the same radio path.

Hi Dave, Richard, and Cecil,

Richard, I checked the url you gave above and the thread I initiated on the 14th or 15th doesn't appear there either. Evidently it's gone--disappeared a little more than a week after being initiated. I've never seen this happen before with any posting. I've often gone back to various posts several months later to review them and they're still there. And God knows I didn't delete my own--I don't know how to do it.

I believe the three postings you said I made are the three that have disappeared, but the one I posted today is there. Cecil said posts can be deleted by the poster, but can they be deleted by someone else? Guess I'll just have to believe mine were eaten by the cyberspace monster and fuhgeddaboudid.

Incidentally, Richard, which paper did you re-read that you called 'sourze C'?

> Thanks, Ralph.
>
> Chuck
>
Now you seem to be getting what I was trying to say. For example if I feed
a sound card output into my Icom 706 and have it set for AM then a receiver
has to be set up for AM to receive the AFSK I am generating at the RF output
of the rig. Same as for FM.
If I then switch to SSB. I will now be generating FSK at the output of the
transmitter. I can slso put the Icom in the rtty position and feed data
into the data port and it will generate FSK by directly varing the output
frequency. This is the same result as using the mic input to the Icom and
using ssb.

I have not looked at the rules lately but it used not to be leagl to use
AFSK below 50 mhz. That does not mean you can not use a sound card, but you
must have the rig in the SSB position so the resluting transmission will be

FSK.

About 20 years ago I was using a ST-6 into a 220 mhz FM transimtter along with about 20 others in the local area. By switching the audio leads to the low band rig, we could also use FSK by running the lowband rigs in the lsb position.

#2

Sorry to report that as of Sunday Mar 6, several of my reference pages are no longer found on my web page. I am investigating as to the reason for their disappearance. It's especially disturbing that the pages referring to the quadrifilar helix antenna research are among the missing. I will get the missing files back on the web page as soon as possible.

Sorry for the inconvenience to those who are looking for the QHA data.

#3

As of 3-13-05 my web page is up an running again. There has been a modification to make it more friendly, and with some new added material. During the next few weeks I will be placing even more information on the page that I hope will be entertaining, and it will also include historical material concerning early space exploration.

My new email address is there for those of you who have questions.

Enjoy.

Walt Maxwell, W2DU

>>> dB

But the forward pattern DOES change with a YAGI design. In fact it inferes
unequal pressures within the pattern. I would have no problem with a lot of
what you say
BUT the YAGI does not follow the theoretical aproach that you supplied thus
what you say regarding a yagi is based on a straw man augument.
My question was for the Yagi pattern which does not follow your aproach
You cannot relate gain and power since with a yagi tho power is an all
encompasing term
(three dimensional) gain is not. What you stated earlier regarding gain as a
ratio
is correct but for a Yagi its parameters must be defined which is not by the
term power.
as you have used it.

(2:1 power ratio increase). You *cannot* have more, as this would
>>> require that the antenna be radiating more power than it receives from

> portion of that hemisphere...
For the isotropic aproach which has little relationship to the real world of
yagis
that some how narrows not only the main lobe but also the other lobes all
of which have seperate gains created by the movement of energy from the rear
and not constrained by your theoretical 3 db aproach

in other words, unless is starts

Oh come on Dave, don't twist things around. I have stated that my antenna,
which is not a yagi, when transposing pattern volume from the rear to the
front
does it in an orderly fashion by expansion of the receiving vessel in a
circular form.
. Thus the gain increased as the rear volume decreased with a diminishing
increase in gain.
The yagi does something different as other vectorial interferences is
creating
"outward pressures" on the so called balloon to NARROW the beam width.
Disregarding any effects that can be attributed to other antennas my
question is
related to the YAGI design which actually creates a narrowing beam as
progress is made
in transposing energy from the front to the rear. This is a fact , thus the
question "why"
a question that is pertinent to the YAGI design and not any other design or
multiple
arrangements of such..
You have supplied plenty of dots regarding antennas but none that remotely
relates to the question

>
>>The question however, is specifically related to Yagi's
>>and its narrowed lobes.

By all means put me on your kill file. I asked a simple question and you
want to reply to a different question of your liking and place your
question
as one preferable to mine.
No one has been able to supply the answer to my question,

Using your words ,what steers the pattern away from a circular
form from a natural circular form. I am not asking for the extraneious
information
that all feel they are compelled to supply to make their posting look
informative.

Great! I would disagree with respect to "any other type of directional array
but I would like a further insight to the mechanics of vector array that
produces
this phenomina. I would like to reproduce this effect else where if I could.

Suggest you get this background from a good read of just about any of the many antenna textbooks available. It's a bit much to deal with in a NG forum.

Hal I think you are right
It is magic!.
I think that this subject has been pushed to one side during the last
century in the event
anybody should come along and say all is known about antennas
so we can put them in their place.
Someday, someone will come along with an answer and then we can all jump on
him
and ask him to prove it so the monkey is not on our backs.
The post did attract a lot of interest tho even if there was not a cigar
supplied.
It really is amazing what photons can do when they become all entangled.
Time to get back to what SWR really entails when all can put their two
pennies
worth in.
I've got to now draw a circle with a compass and observe how the shape
changes when
replotted with logrithmic and other types of graph paper

If you can't see the value in amateur radio than you are a idiot. anyone who thinks it's ok to operate in a band they are not licensed to be in because they are doing something good is messed up. what's worse is if you think it would be ok to give up the band because a trucker is doing something productive? geez.. Listen around there is ALOT more going on the amateur bands than pure recreation.

There are a few balanced tuners available for purchase. I assume you just want the building experience? If not, Johnson Matchbox tuners are sometimes available on Ebay and other sites. And MFJ has two current models. And Palstar has one current balanced tuner.

Good luck, jimbo

Be sure to give us a report on creating the logarithmic graph paper.
If I heard someone was looking to replot circles on log graph paper, I would say he must be a ham.
Then I would think about writing a Java program to do it, as I slipped into sleep while listening to 'Coast-to-coast-AM' on the radio.

>question
>as one preferable to mine.

Art, in cases like this, you keep asking "simple questions" which imply, by their very wording, a whole bunch of assumptions about how things work which just ain't so.

The fact that you keep getting answer after answer, from a lot of knowledgeable people, which you either don't understand or "blow past" or that you feel evade the point of your question, ought to be saying something to you: that there's something wrong with the questions you ask.

>No one has been able to supply the answer to my question,
>Using your words ,what steers the pattern away from a circular
>form from a natural circular form.

That depends on what you mean by "a natural circular form."

If you're referring to the fact that the main lobe of a dipole tends to look circular on many of the commonly-used plots, then the pattern isn't "circular" in any cosmic sense of the word. It's just as correct to say that it's elliptical, or bumpy, or squashed, because that's exactly how it will look on plots which use different circular axes (linear, logarithmic, etc).

To try it again, though: you're asking why the pattern appears to be compressed, as the gain increases. Fundamentally, it's due to the fact that the antenna is sending more power out in the desired directions (more gain), at the expense of sending less in other directions. This is done by creating multiple radiators, which are offset in power and location and phase so that their individual radiation wavefronts reinforce in the desired directions, and cancel in the undesired directions.

When we plot the resulting RF strengths, the RF in the desired direction is stronger (we got the gain that we want). Let's assume that (as is common practice) we continue to plot the signal in the strongest direction on the outer circle of the graph.

Now, one of two things will have to be true:

[1] Every other direction in the main lobe had its power "scaled up"
by the same amount... the increase in gain worked the same for all
directions within the main lobe. In this case, the shape of the
main lobe will not change at all.

In this case, the additional power required to achieve the
increase in gain in the main lobe will have had to come for
somewhere. Since it didn't come from the main lobe, it will have
had to come either from the sidelobes, or from the rear half of
the antenna's pattern.

There's a limit to how far you can take approach [1]. It stops
working when your sidelobes and rear half of the pattern drop to
zero... and it becomes rather ineffective some time before that,
when the largest of the side/rear lobes is maybe 10-15 dB down.
Beyond that point, there just isn't enough power left in those
backlobes to be useful.

[2] The other possibility is that you didn't manage to boost the gain,
uniformly, in the entire main lobe.

In this case, if you're still plotting the strongest signal on the
outermost circle of the graph, you'll notice that the shape of the
main lobe has changed. Any direction in which the gain increase
was less than the maximum you achieved, will be closer to the
center of the circle than before. [Another way of looking at this
is that by increasing your maximum directional gain, you've
"enlarged the circle" on which you're plotting it, but that some
points didn't move outwards by the same ratio.]

In the common case of a Yagi, when you boost the gain (say, from 10 dB
to 15 dB) there just isn't enough power available in the side and rear
lobes to make up this gain... you can't 'rob' enough directivity from
the sidelobes and rear lobe. Instead, you 'rob' the power from the
outer edges of the main lobe, and shift it in towards the center.

You do this, most commonly, by adding additional parasitic elements,
whose location and phasing are such that their radiation reinforces
that moving in the "forward" direction, and interacts destructively
with (cancels) radiation moving outwards at an angle.

When you plot the resulting pattern, and scale it so that the
strongest signal is on the outer circle of the plot, you find that the
main lobe looks narrower. Part of this is due to the actual
redirection of power, and part of it is due to the fact that you've
re-scaled the graph.a

. I am not asking for the extraneious
>information
>that all feel they are compelled to supply to make their posting look
>informative.

[invokes several wrathful deities...]

Art, if you continue to ask "simple questions", and you continue to
get back complicated and detailed answers, it really ought to convey
to you the possibility that your "simple" question is oversimplified.
Or, perhaps, that you've been given the actual (simple) answer three
or four or five times already, have rejected it, and people are trying
to explain to you why it's actually correct.

Goodbye, Art. This is/was my last attempt, I think. I doubt I'll try
again.

You'll need a balun whether or not you use a balanced tuner.

That is unless you have a balanced transmitter.

You can save yourself the cost of a pair of ganged inductors by
inserting a choke balun between the balanced feedline and an ordinary
unbalanced tuner.

Hal
Amateur radio operators have been convinced to display radiation patterns
on logarithmic paper to make it look more directional than normal plotting
procedure.
Since I can now generate a complete circle for an non yagi antenna array
using logarithmic paper on my antenna program I thought it would be
interesting to see
what a circle would look like when using 'standard' graph paper.(a reverse
procedure)
Now, as I write this, I realise that my antenna computor program has the
ability to
make this transition.
This will be interesting as I have no pre-expectations as to what it will
show.
Best regards
Art

The whole purpose of the choke balun is to allow the ordinary tuner to
be safely grounded.

The tuner is grounded automatically by virtue of its short connection
to the unbalanced transmitter.

Or have I misunderstood you?

Using a antenna computor program the main lobe at 10 degrees does not
deviate from a circle even if the F/R is more than 30 db (note F/R vs F/B)
and this is comprised of vector addition mode as with a yagi design.

>
> [2] The other possibility is that you didn't manage to boost the gain,

No, not always, only with a yagi design in my opinion

Any direction in which the gain increase
> was less than the maximum you achieved, will be closer to the

Now we are getting closer to my quest. How do we "rob" from the outer
edge of the main lobe is the underpinnings of my question.

>
> You do this, most commonly, by adding additional parasitic elements,
> whose location and phasing are such that their radiation reinforces
> that moving in the "forward" direction, and interacts destructively

Agreed if we are adding or subtracting on a constant plane.
Could you by any chance referring to the closing vector of the vector
analysis
to consist of two vectors and where one of these vectors is the force at
right
angles to the main lobe and which deforms it. If so I am beginning to see
the light!

>

I am lost here but if we agree on my interpretation of what you said then
I am at a point where I can generate vector diagrams of different arrays
and forecast the width of the resultant lobe .Does anybody else agree
that the main lobe width can be forecast via vector analysis.
Seems like from past posts that vector analysis is not now in vogue
for electrical engineers in the U,S and only creates blank stares
when mentioned/
.

>to the unbalanced transmitter.
>
>Or have I misunderstood you?

It depends. There are two arrangements using choke baluns that I'm aware of - balun at the input, and balun at the output.

It's fairly common to put a choke balun at the output of an unbalanced tuner, to convert the unbalanced output to a balanced form. This seems to work pretty well when the tuner is looking into loads that aren't too high, low, or reactive in nature. For high-R or highly-reactive loads, it may be difficult to create a choke balun with a high enough choking reactivity to force adequate balance on the line. In this approach, the tuner can be connected to the transceiver via a direct cable, and its chassis can be connected to the station RF ground.

The other approach is to put a choke balun at the input of the tuner, "float" the tuner chassis clear of ground, and connect the balanced line directly to the "unbalanced" output of the tuner. This pseudo-balanced arrangment can provide good balance once the tuner is adjusted, because the balun "sees" 50 ohms on both sides... but it adds the complication of having to float and insulate the tuner. I've heard of some people taking a commercial tuner, and putting it on insulators inside a secondary outer chassis. The outer chassis can be connected to the station ground, and or to the transceiver coaxial feedline braid _before_ going through the choke balun.

Well, I guess the FCC could increase the cost of licences by about 10000% to cover the costs of enforcing this for a very small number who would benefit--but don't hold your breath...
Sure, most of those truckers are running 500+ watts and I have seen 1500 watt linears being built by a retired engineer in his garage (mobile linears!) for extra beer money...
But hey, those truckers are in most towns and cities for a matter of minutes, they don't get paid unless they are laying down miles on a road--they are only temporary inconveniences...
"Radio Police" running up and down the freeways pursuing truckers seems to come in low on a list including terrorists, illegal aliens, a failing SSI system, increasing drug and medical costs, etc, etc--the danger of being sued for illegal searches alone is scarry... not to even mention how ridiculous it all sounds to people outside ham radio!
Becomming totally involved in a hobby to the point of losing all sense of importance of reality is fine--I like to day dream--but get real!

Regards

Not so. If I cannot accept an answer that I figure to be unreasonable then I do not accept them. In Roy's case I accept
the majority of his explanations, but not all. In your case you come up with many knoweledgable explanations
on various facets of science ,but in general, you concentrate more in attacking others opinions with out supplying corrections
I say this only where your posts are clear and not smattered with relatively unused words where a shorter one would suffice How ever those are in the minority.
If I do not concurr with any explanation offerred .in no way does this suggest that I am spitting on the individual and thus treating him with disrespect. In your case you treat me in disrespect which as far as I am concerned requires reciprical treatment. You ask for it and you will get it from me without retreat On the other hand respect demands respect, your choice as I am now americanised for retaliation without regard to common courtesy as per the Britts

Using a computer program automatically incorporates all the defects in
the programmer's reasoning and understanding of the problems
involved - plus other bugs.

Never use a computer program as the Bible.

Tom, now you are being silly.
You obviously do not know all about antennas other wise
you would be anxious to display your knoweledge as to why this is
impossible.
But then you can't and thus want to assault the messenger.
I could present the facts to an individual for confirmation but this would
only mean
a deflection of comments from me to the adjudicator from people with the pre
disposition of yourself

I could not agree more This is why I requested comment on my computor
findings.
It is easy to generate a program to agree with what is known to all.
It is another thing to pre forecast results from an untried array.
It appears from comments given that the computor programs are not to be
fully
accepted, especially if a lobe pattern produced is circular in nature and of
various thickness
Tho I must admit I am unaware of what text books they are being guided from.
,

Nope, I don't know everything, but I do know the amount of energy
radiated can't be more than what the transmitter outputs, so the sum of
energy around the sphere has to equal that. If you think you can make
the main lobe broader, then you are implying that you can radiate more
powwr than than was originally there.

Freebanding is the least of my worries with truckers. Big trucks are 5 percent of the vehicles on the road. They are involved in 25 percent of the accidents. Naturally, they blame this on the cars. The corrupt federal, state and local governments are paid off by the motor freight (fright?) industry to look the other way on speeding and almost all other infractions. When was it last time you saw a truck pulled over? How often do they go by on the highway in excess of 75 MPH? Do the math.

Of course, as a ham, I also despise freebanders and hope they get caught and fined - big time.

Russ

so what is more inportant in life not your hobby most people put there
radio hobby before,god and there family that is sad .they will drive all
night to go to a hamfest but when it comes time for a family event o i
cant make it heard it to many times on the radio waves.
so i guess the ups or fedex truck did not bring you that new hf rig so
next time you pick it up stop picking on truckers.

Goodness me, do you really think that is in quesdtion in this debate ?

If you think you can make
> the main lobe broader, then you are implying that you can radiate more
> powwr than than was originally there.

You really are jumping the Grand Canyon in TWO strides !.
I have no idea what you are saying or alluding to.
To make something broarder is describing one dimension only.. less if used
in ratio terms
To describe energy one must have more than one dimension or unit.
Surely one must know this to graduate from High school in the U.S. or am I
mistaken.?
If so it then accounts for some of the wierd responses that have come my
way.

A friend of mine, in a restricted Southern Ca. location installed a flagpole (he needed special permission from the Association's Architectural Committee for this). Then late at night we added buried radials and a feedline. It works reasonably well 40->6 meters with the help of a tuner. It would work better with a remote coupler, of course.

This is the Force 12 version, but I don't think it makes a whole lot of difference.

My post was simply a list of facts as they appear to me. The use of
communications to assist in the delivery of medicine, food, clothing,
building materials, etc. is of more importance than the use of airways
for
recreation.

That might mean something if they actually needed it, or didn't
have a legal choice. But they do. Regardless of feelings on the
matter, what they do is illegal, and could cause them considerable
negative cashflow if caught. Could also effect the ability to
legally obtain a license after such a conviction, the way things
have been going lately.

Since most would accept that the law of "...the greatest good for the
greatest number..." would apply, if push came to shove--the truckers
would
probably end up with the frequencies in question...

They have legal frequencies they can use. This is *exactly* what
the CB band was created for. They also have business band options,
the the family radio frequencies to chose from. Myself, I have a
simple solution that I impliment when I hear illegal truckers on
the CW portion of 10m. I fire up my henry console, and started
calling CQ right smack dab on top of them. Tends to ruin
their day...1+ kw of CW on 10m cuts holes like a plasma
cutter...:) I have no real problems with them using the
"freeband" under 28 mhz, as it's basically unused, although
legally, it is allocated to aircraft I believe... I'll
leave it up to the FCC to decide how they want to treat it.
As far as I know, they will prosecute, if they hear you
there. The "freebanders" have been there for so many years,
they have sorta of taken it over...
But if I catch them in *my* allocated frequency range,
I'm gonna put them on hold. They can try to talk,
but I'm going to make it as unpleasant for them,
as possible. It's called self policing. And that's
the way ham radio has basically been run for years.
If the truckers want to use 10m, more power to them,
but they better get a license first. And being it's
so easy these days, with CW being snails pace, even
for extra, there is *no* excuse not to have one.
They can use 2m, if they are too slow to learn CW.
So even CW is no excuse to break the law. MK

....Anyone ever done a helical wound "Slim Jim?"
yes.
Since this is a 1/2 wave
antenna with a 1/4 matching section (3/4 overall),

Why the 1/4 matching section? Seems that takes it
nearly to the full half wave length...or close
enough not to matter much...
Myself, I would probably prefer a "gamma loop"
type matching scheme, which adds no height.
To me, 16 ft tall is no more trouble than 12 ft tall
in the real world.
I've had a lightweight 32 ft self supporting radiator
up, which was no hassle at all...And the base of that
was at 36 ft on a mast. "68 ft tall total".
That was a dual band 40m GP/ 17m 5/8 GP....Full size
on both bands, relay switched.

helical winding of this form into a 3/8 overall height
(approx. 12 ft. @ 28Mhz) might be possible.
The extremely low angle of radiation (approx. 8 degrees)
would make this vertical antenna desirable... .....

The angle of maximum radiation will vary fairly
drastically depending on height above ground.
For a "like" sized vertical, the height above
ground will have more of an effect, than any
extra electrical length. To my way of thinking,
the advantage of the extended winding should be
the largest, the closer to ground it is.
The higher above ground, approaching 1/2 wave up,
the lesser the advantage.
Note that at high heights above ground in WL,
the 1/4 wave ground plane, and the 1/2 wave
vertical have nearly the same gain for practical
purposes. "maybe .3 -.8 db difference..."
You should consider decoupling of the antenna
from the feedline also. Radiation from the line
will skew the pattern upwards off the horizon.
This will ruin even higher gain collinears.

I like my antennas full size if at all possible.
I'm a radio bully. :/ MK

Hi Dave and all,

For Reg. I've used the method that Dave speaks of above over the years
with very good Sucess but as he says the tuner must be isolated from
ground in order to produce the needed balance at the out put. The
advatage as stated is that the Balun (once the turner is tuned to the

frequency being used will see pretty much 50 ohms on both sides. It has work very well here .

Some things that Albert Einstein said sound a lot like Art.

"Imagination is more important than knowledge."

"Education is what remains after one has forgotten everything he
learned in school."

"All our science, measured against reality, is primitive and
childlike ..."

"As far as the laws of mathematics refer to reality, they are not
certain, as far as they are certain, they do not refer to reality."

"Whoever undertakes to set himself up as a judge of Truth and
Knowledge is shipwrecked by the laughter of the gods."

"Great spirits have always found violent opposition from mediocrities."

"He who joyfully marches to music rank and file, has already earned my
contempt. He has been given a large brain by mistake, since for him the
spinal cord would surely suffice."

It is interesting that so many intend that you "design the world" then cause the people to fit the design; this is 180 degrees of what really happens--people bend the world to fit themselves.

For whatever reasons, some have seemed to have decided certain "rf space" fits them and, they are no small number, the truckers!

While it might benefit some, if there were "radio police" to hunt down every trucker with a 500+ watt linear, who would pay for this? Would hams accept a 10000%+ increase in the cost of licenses to help fund such a force, equipment and activities?

And, it is one thing to find a station running at a stationary location--quite another when that station is mobile. However, those enjoying such things would find one large and unending fox hunt--reminiscent of the old "cops and robbers game" one played as a child!

Imprisoning citizens for simple infractions of rules which are causing no one physical, monetary or real personal damage (i.e. amateurs are only being deprived of sole benefit of bandwidth for their hobby use) is insane--you have to wonder "what are these people thinking?"
One very good example of this, and could be viewed as a model of what would happen if this were to occur might be "the war on drugs." We have waged this war for 30+ years--there are more drugs on the streets than before we began--and people are REALLY being harmed NOW as these criminals attempt to gain the money to obtain the drugs we have made so expensive and, to escape the penalties we have made so severe--INSANE! There is about the same amount of cocaine in a coca plant as sugar in a sugar cane. I can walk into a supermarket and buy 5 lbs of sugar for next to nothing! If that were cocaine, it would probably get everyone in a major city high, maybe for days! Since it is forced to the black market it most likely costs millions!!! And, there seems an unlimited amount of addicts which will maim, harm or even kill citizens to gain this drug--INSANE!

There was a time when one special group of a few individuals could be allowed to think themselves "special" and allowed to run a unique "old boys club." Times have changed. However, you are living in the past if you don't see the handwriting on the wall and, think you will be able to oppose change and evolution of the use of radio communications.

Some will personally attack me for pointing this all out-kill the messenger bearing the bad news-WAKE UP! Look around, you are either part of the problem or you are part of the solution...

When you are done acting like a child and throwing your temper tantrums-perhaps you will see the problem is still there to deal with.

Regards

There's considerable debate on that configuration. If we assume
the common-mode current doesn't change when we move the choke
from output to input, i.e. it is a systematic problem, then the
choke is exposed to exactly the same common-mode current on output
and input. Common mode current travels on the tuner chassis and the
coax shield input and coax shield output may be one inch from each
other with a dead short between them.

And here's something that no one, to the best of my knowledge,
has mentioned. If one succeeds in balancing the currents at
the input of an unbalanced antenna tuner, the currents at the
output will automatically be unbalanced because the current on
the coax center wire will suffer a greater phase delay than
the current on the coax inner braid thus forcing some current
to the outside of the coax. This effect should be easy to measure.

Link coupling solves the common-mode problem. Unfortunately, the
MFJ balanced tuners do not relieve the stress on the choke. Take
a look at the schematic to see why.

Not at all. My usenet service provider allows me
to delete my own posts. That's useful if I typo
"1/2WL" instead of "1/4WL" or some such.

The reason OK lost is because, despite AZ's off-night loss to IL and
their friends the officials and the crowd, they were up against the
best team in college basketball.

Our biggest guy, Channing Frye, is listed variously as 6' 10" or 6'
11".

Have you looked into the Moxon or X Beam designs? There is also a
drooping yagi where the elements of the yagi are fixed length, but a
wire is hung on the ends of the elements to keep the lengths of the
driven and reflector elements properly resonant. Additionally, you
can try linear loaded elements for the beam.

If it is small and directional, you better choose a portion of the
band and focus on that. I don't think you will find too many wide
band shortened beams.

How critical would the matching on those beams have to be? I am
wondering if maybe a 300 ohm wire could run from DE to DE on the two
beams.

While I don't support people who threaten harm to others, neither do I respect the "I am going to tell the teacher" types.

If you wish your ISP to be anonymous go to this web page, find an anonymous host of your choosing:

http://www.atomintersoft.com/products/alive%2Dproxy/proxy%2Dlist/

|-------
address -------|- port-|

the ISP address will be give in the form XXX.XXX.XXX.XXX:XXXX

using the address and port, open IE Explorer.

- go to "Tools"

- then "Internet Options"

- then "Connections" tab

- then "LAN Settings"

- check the "Use proxy server for you LAN" and enter the above address and proxy into the appropriate boxes.

- Pick "OK", then "OK" again

Now your browser should be set to proxy through the ISP proxy you have entered into IE Explorer. I leave it to you to make sure it is set correctly, there are many pages on the web which will test for you and show you the ISP that being displayed as being "yours."

If your settings in outlook express are to use the settings from IE Explorer, this will make your postings and email appear to come from another ISP which is NOT your real one-effectively making you anonymous..

No one should be able to say this is "illegal." It can simply be looked at as sending a letter to someone and NOT including a return address on the envelope-or, using an invalid address to protect the innocent.

Posting, and voicing ones thoughts should not be open to retaliation by vengeful people who would harm you.

Knowing Pi out to seventeen places neither validates nor refutes the
shape of a pie. The evidence of correspondence proves my point: it
doesn't really matter given the greater bulk of your responses lie
outside of technical offerings - such data rich marginalia still fails
to elevate its pretenses above a trivial concern.

Many truckers are smart enough to become hams and have done so. So
why can't other truckers do the same?

Truck drivers may do a good service, but they do a dis-service when
they freeband.

There are frequencies assigned for those kinds of purposes, not
amateur frequencies. Try using a cell phone etc. Besides, they don't
need the ham bands to deliver medicine etc.

Oh yeah, I forgot... if this proxy you entered ever becomes unavailable, you will NOT be able to connect to the web. SO... remember to either go back in IE and turn off the "Use proxy..." box using the above will guide you there... then you can simply go back to the proxy web page, get a new address of a new proxy and plug it into IE Explorer... you should change the proxy you are using, frequently, anyway...

Regards

<SNIP>

The SlimJim resembles the J-Pole. The 1/4 wave section is a matching
network and it is probably not critical that it be vertical so the
height may be reduced by about 1/3. I am not sure what the folded
section does for it. but without the 1/2 wave section coming back
down from the top, the antenna is just a J-Pole.

Hi Albert,

I presume by this "range" that the beagle moves unhindered WITHIN the range of the antenna, and outside of this range she gets a shock (or some form of behavior modification).

If that is accurate, then boosting range would accomplish your goal. The problem I had was presuming that the antenna was at the perimeter, and if your dog penetrated towards it, entering its field, that this would "modify" her behavior. I am more familiar with antenna perimeter fences were a collared pooch approaching such a fence would be -um- stimulated.

Anyway, as you have already noted the design of the transmitter and the antenna both, then you have options with both. Using the same antenna, you could feed your transmitter into an unused stereo (or monaural) amplifier and use that to drive the antenna with more power (say 1 to 5 Watts). Then you could adjust the range with the volume control. If this worked, you could then go out an buy a dedicated audio amp kit ($10-$20) that fits this power range.

Another method is to replace the antenna with conductive stakes driven into the ground. At this frequency, ground conduction has a fair range. It was one method of communication that was used with trench warfare during WWI. The further apart the stakes are, the better. I would add that this comes with some shock hazard and is certainly not within the warrantee of the product (but nothing suggested here will be). As this a strictly an experimental long shot, try the simpler suggestions above.

4407. Insulated Wire Velocity Factor: How to . . ??

Newsgroup: rec.radio.amateur.antenna
Date: 2005-03-28 19:52:23 UTC
From: Brian Kelly <kelly@dvol.com>
Message-ID: <1112039543.240538.184890@f14g2000cwb.googlegroups.com>
Source record: 80052

I'm in the habit of using insulated stranded all-copper conductors for HF wire antennas. Usually U.S. standard #14 Type THHN "house wire" because of it's easy availability everywhere at low cost. However insulated wires pose an annoying problem, their specific velocity factors are not published and vary all over creation depending on a whole collection of variables.

I've tried to nail down the Vf of my usual #14 THHN by cutting the lengths of 20M dipoles to one or another of the usual equations. I put together the antennas, hoist them to various operatng heights and nip the coax feedline to it's minimum possible length so that I can find the resonant point with an antenna analyzer while I'm on the ground directly under the feedpoint. A process which I believe should lead me to a "correction factor" from which the Vf can be determined.

Modeling a 20M dipole at 35 feet indicates a fairly sharp null at the resonant point. But that's not what I get when I build the antenna and try to measure the frequency of it's resonant point with an antenna analyzer. I get a much flatter SWR curve from the analyzer than I do from modeling probably because of feedline losses and because of the low analyzer frequency resolution (MFJ-259B). To the point where the antenna appears to be resonant over a range of maybe 200Khz. Which in reality it can't be.

>From a practical standpoint this scenario isn't any problem in the case of a simple dipole. I "cut long", put the antenna up, sweep it with the analyzer, find what seems to be the center of resonace, do the quickie numbers, trim it and take it to the airwaves.

The problem comes when trying to accurately model complex, fussy wire antennas like hex beams when the Vf of the wire is unknown. A one percent error in conductor length at 14 Mhz is 140 Khz which makes decent modeling just about useless.

So two questions in this regard: Is there a way to measure the Vf of a wire without having to resort to using 2" Heliax to feed a dipole and without a lab full of HP and GR test equipment? Second, assuming the Vf becomes known how does one handle it during the modeling process? Model the antenna wire lengths at an upward-shifted frequency based on the Vf?

Thanks,

w3rv

>driven variable-link coupling. Too bad it runs
>on 28 vdc.

I'm not sure that there's any single answer to that question.

Comments on eHam.net from owners of the old Johnson (or Nye) Matchbox link-coupled tuner seem to suggest that it's capable of operating with low losses - significantly lower than are achieved by some of the unbalanced T-configuration tuners mentioned.

I suspect that the efficiency depends very much on the design and implementation of the tuner (e.g. air-core coils vs. a toroidal design, size of core, degree of coupling between the tank and the link, wire gauge) and on the specific impedance being matched.

Based on what I've read about Z-match tuner design, it seems that close coupling across the inductive link helps boost the efficiency. However, the close inductive coupling tends to come with an increased amount of capacitive coupling, and this can apparently affect the output balance for the worse in some cases.

I suspect (but don't know for sure) that link-coupled designs which use a fixed-position, tightly-coupled link (e.g. an air-wound or toroid-core Z-match) may be more efficient than those which use a "swinging" link with variable coupling.

Hi Brian,

1. Drive the design with power instead of low level excitation;

2. Remove half the transmission line muffling of results by using a
field strength meter to find resonance (another reason for power);

3. Find the Vf (as you put it) by derivation against a wire model
(through the difference in lengths of bare wire model resonance to
real wire resonance);

4. Use the new EZNEC which allows you to employ insulation over wire
and adjusting the thickness to conform with results found
experimentally with real wire at actual length;

5. Assign these insulation properties to all future designs in the
modeler.

The Slim Jim appears to be identical to the "top wire double radiator"
J-pole which is described in Cebik's multi-part discussion of J-pole
designs: see http://www.cebik.com/vhf/jp2.html

His analysis suggests that the performance and behavior of this type
of J-pole are essentially identical to those of a single-radiator
J-pole. There are some slight changes needed in the antenna
dimensions to get it resonated properly (the coax attachment point is
a fraction of an inch higher up and the total length is a bit
different) but once those are taken into account there doesn't seem to
be any real difference in performance between this variant, a
version with two wires which are left unconnected at the top, and a
version with one wire.

At their best, they appear to be simple 1/2-wave radiators. The hype
on the HamUniverse page about this antenna outperforming "1/2wave over
1/2wave over 1/2wave colinear!" seems a bit overdone - if it's ever
true, it would be in comparison to a rather badly-done colinear!

My expectation is that one could create a helically-wound version of
any of these J-pole versions. The matching arrangement would no doubt
need some adjustment. I'd expect the gain to drop off, with more
high-angle radiation appearing, in the usual fashion as the total
length of the radiating section is shortened.

I might be missing something here, but wouldnt increasing the range of the transmitter/antenna combination reduce the amount of room that the dog has to run in? Increasing the range, would trigger the collar when the pup was farther away from the perimeter - confining the pooch to a smaller area.

What is the design of the reciever on the dogs collar? You don't have to increase the range of the transmitter, you could just increase the sensitivity of the receiver. If the xmitter is really running at about 17khz, then a 1/4 wave whip (about 2.75 miles) attached to the dogs collar might work. If that does not work, you could at least reel the dog in when she gets a bit too close to the road.

Buck wrote:
"How critical would the matching of those beams have to be?"

Very.

Recall that a perfectl;y matched antenna delivers only 50% of its received energy to its load. The other 50% is re-radiated. In the case of back-to-back antennas, the load of one antenna is the other antenna. The source resistance of one antenna is the antenna resistancce of the other antenna.

If one antenna is shorted or open, 100% of the energy it receives is re-radiated.

So if all antennas are in far-fields, and if all antenna connections are lossless, and if all antennas are properly aligned, and if the match of all antennas is perfect, overall system gain is the sum of the antenna gains minus the path losses (both paths with a pair of antennas back-to-back). Recall that the radiated signal loses 22 dB in the first wavelength and 6 more dB exery time the distance doubles after that.

Best regards, Richard Harrison, KB5WZI

If you have a MFJ-259, you can get the VF of the wire easily
or
1. put up a 10-meter dipole using bare wire - note the resonant freq
2. duplicate exactly using 14 THHN Str - note the NEW resonant freq.

divide the resonant freq from step 1 by the resonant freq from step 2. (or is it the other way around)

Anyway, I don't think you have to add your social security number.

4421. Re: Narrow lobe of a yagi

Newsgroup: rec.radio.amateur.antenna
Date: 2005-03-29 01:43:46 UTC
From: Hal Rosser <hmrosser@bellsouth.net>
Message-ID: <Gj22e.67682$6g7.13747@bignews1.bellsouth.net>
Source record: 80066

AHA - now we have the answer to the problem of narrow yagi lobes.
We are simply using the wrong graph paper to depict the pattern.
I'm sure that with enough planning and dedication, a committee of a few
dozen could come up with a special graph paper, custom-made to your yagi
such that no lobes would seem narrow at all.
In fact, your yagi could become the perfect isotropic radiator.
THAT's the ticket.
For a 'more fun' way to plot yagi lobes, you must use a field strength meter
and a motorcycle and a blonde.

> I am not sure what the folded section does for it.

Folding a 1/4WL vertical raises the feedpoint impedance.
Folding a 1/2WL vertical lowers the feedpoint impedance.

A folded 1/2WL monopole has about half the end-fed feed-
point impedance of an end-fed single-wire 1/2WL monopole.
About 1250 ohms Vs 2500 ohms for 20m with mininec ground.

EZNEC sez the folded 1/2WL monopole has a slightly lower
resonant frequency and slightly higher gain. (+0.07 dB)

Well, I hate to say it, but with the price of oil, some day that may happen.
IF SO, we'll have to resort back to what our Pioneer forefathers did when we
didn't have "toilet" paper. SO, there IS an answer to most any thing your
truck can do. OR fails to do.

Well, let's hope that the idiots they are continue to drive above the
speed limit, ignore safety laws, cook the books, and kill lots of
innocent citizens. They seem to like that life, and we, as normal
humans should not deny them it.

An 1/2WL end-fed with 1/4WL matching section is a Zepp.

Well yea, I realize that...But I think it's a silly
way to do things, if height is an issue...Unless maybe,
it's some kind of parallel stub as in a J pole...But
I would think that would be sort of silly too...

The SlimJim resembles the J-Pole. The 1/4 wave section is a matching network and it is probably not critical that it be vertical so the height may be reduced by about 1/3. I am not sure what the folded section does for it. but without the 1/2 wave section coming back down from the top, the antenna is just a J-Pole.

Yea, I finally realized that, after Cecils reply.
I would still prefer a gamma loop feed I think...MK

Hi "Fred,"

It will take more than supposition and superstition.

So back to rote:
The physical size in relation to wavelength dominates launch
characteristics, NOT electrical length.

I auume these thing work in reverse of conventional thinking. I assume that as long as the receiver is receiving a signal, the dog does not get shocked. If it strays too far and the receiver loses the signal...ZAP! However, modifying the transmitter would violate its Part 15 certification and the owner might be the one to get the ZAP (from the FCC)...

OK, then this is very different from other "invisible" fences that I have seen. It would appear that this device is designed to keep the dog close to the transmitter, and then shock her when she strayed too far - when the receiver on the collar lost the input signal.

I think that device would not give you all that much control as to what kind of coverage area you can have. Also what would happen if the collar lost the xmitter signal due to other reasons (dog goes behind a trash can/metal shed/other large metal object)? Personally, I would return it, and get the type that used a buried wire -- or just train the dog not to stray too close to the road by other means.

That being said, it might still be easier to increase the sensitivity of the receiver. What type of antenna is on the dogs collar? Also - what is the brand and model of this unit? It might make tracking down the soultion a bit easier.

I don't know who wrote your rote, but here is part of what Terman says on this topic in his Radio Engineer's Handbook, p 795, referring to vertical radiators driven against ground:

"Top loading has the same effect on the field distribution in a vertical plane as a greater height. Thus an antenna for which H = 0.45 lambda can by suitable top loading be made to have a field distribution in the vertical plane that is substantially the same as for a vertical wire of H = 0.6 lambda."

Or is that what you meant?

RF

4440. yagi boom question

Newsgroup: rec.radio.amateur.antenna
Date: 2005-03-29 14:56:43 UTC
From: francesco.messineo@gmail.com
Message-ID: <d9f2bc2.0503290656.2e0b3837@posting.google.com>
Source record: 79985

Hello,

I've built several yagis until now (most of them based on the famous DL6 design).
Almost all of them are of the not-insulated elements variant, the last one
is instead of the insulated through the boom type. It's a 9 element for 144 MHz
and it gave me good results. No part of the boom is in electrical contact
with anything else but the support pole, the radiator is a folded dipole with
4:1 coaxial balun. Now I'd like to understand if it would be better to connect
the boom to the coaxial screen or to the center of the folded dipole or leave
it completely insulated (and also why it is so...).
Another question: has anyone calculated elements' corrections for
not circular booms (square section or rectangular section)?

Thanks and best 73

Francesco IS0FKQ (ex IZ5DWF)

============================

No, it doesn't !

But you could stretch "substantial" (a non-engineering term) a bit
more.

You have been warned once before about quoting Terman as the Bible.
(smiley)

The important point is that the web page claim of bettering
three end-to-end 1/2WL dipoles misses by about 3 dB and a few
degrees on TOA.

Hi Alex,

At 17KHz this is virtually impossible. It would be like trying to
hide behind a house in Aceh when the wave came in.

Art Unwin wrote:
"---what actually creates the narrowing of the forward lobes?"

Destructive interference of energy outside the main lobe lobe which concurrently causes constructive interference within the forward lobe as energy is neither created nor destroyed but redirected.

Highly conductive parasitic antenna elements can approach 100% efficiency. They re-radiate, having no load other than a complete highly conductive short sircuit, nearly all of the energy they intercept.

The re-radiated energy is carefully phased to create the desired directional pattern. This can be "cut and try" or it can be calculate and try.

Best regards, Richard Harrison, KB5WZI

"Reg Edwards" wrote about the elevation pattern of a loaded vertical against ground as being ~ the same as that of a longer, unloaded vertical, per Terman:

> No, it doesn't ! You have been warned once before
> about quoting Terman as the Bible.

I wonder, then, what your basis is for saying so.
At least I give a source.

Terman also publishes a formula to calculate the elevation pattern of a shortened vertical with a top-mounted capacity ring, driven against ground -- but it's too much to post here without mathematical notation. The formula was credited by Terman to George H. Brown from his "A Critical Study of Broadcast Antennas as Affected by Antenna Current Distribution" published in the Proceedings of the I.R.E.

Terman also says that inserting a coil a bit down from the top of a shortened vertical gives results equivalent to using a top mounted capacity ring.

Forgot about the frequency there for a minute ... 17khz is a very long wave

Either way, the whole concept of this specific device seems sort of
backwards for it's intended purpose.

The results are predictable, boringly so, and several have already
been down that road to no net gain. However, common sense in these
matters can be discarded if only someone offers validation, however
slim that may be from any jim. Such inventors stand on the shoulders
of dwarfs. Sorry for the allusion, as it again reprises the obvious
that physical height in relation to a standard (wavelength) dominates
the principle. However as principles and seeking validation go, no
doubt the topic will drift towards top loading dwarfs....

One of the old Firestone HF circuits to EL used stacked rhombics to kill the
second lobe. The high angle lobe was hurting RTTY reception because of the
delay associated with receiving via two propagation modes.
Today's modulation methods and computation power would not be hurt by
such multipath propagation.
I have thought of using such a scheme with LPDAs on receiving so as not
to receive US stations so strongly. Most of the hurtful QRM when trying to
work DX comes from first-hop stations. (I am speaking of on-frequency QRM.)
The benefit on transmitting is unimportant.

Lots of fun to use a pair of the 5 element yagis included with EZNEC to
see the effect of vertical (or horizontal) stacking (broadside array).

Source record: 79998

Many years ago, when costs were quite different:

The British police used a hybrid system to extend the range of their low power 400 MHz transceivers. They found some large almost flat roofs located near the edge of coverage. At the edge of the roof most near to the base station they erected a high gain antenna pointed at the base station. Coax was run to a BPF + mixer + narrow BPF + mixer + amplifier where the LO for both mixers is the same. (This scheme cleans the signal and adds some amplification.) From the active device, coax was run to the distal edge of the roof to a second gain antenna pointing to the sector of interest. Both antennas had grid reflectors/shields so as to reduce to a minimum their "behind" coupling, which had to be less than the gain added by the active device.
The scheme worked.

I have used passive schemes where a high gain antenna on a roof captures signals that are distributed in basements and tunnels through a TL made deliberately leaky. Have coverage where none was available before.

The sub-theme of Richard is that one needs to calculate the numbers to see if such systems will work.

So far you have not provided support for your statements on this subject from any recognized antenna authority. Do you really believe that your understanding of this, and your statements about it are better/more accurate than those of Frederick Terman and George Brown?

> Ted KX4OM

Volume resistivity is a useful measure only at DC.

To determine a dielectric's lossiness at RF, look at the loss tangent, dissipation factor, or power factor. Loss tangent and dissipation factor are the same thing, and when loss is low, power factor is also the same for practical purposes. You'll find these in tables and descriptions of the electrical properties of insulators. Some searching will usually turn them up on the web if you don't have access to the appropriate reference books. Note that the loss properties are usually a function of frequency, so use the value at approximately the frequency of interest.

In some situations, the capacitance of the dielectric can be important, such as when you're using it as a coil form or antenna covering. For that, look at the dielectric constant or relative permittivity (which are the same thing). This also changes somewhat with frequency.

Roy Lewallen, W7EL

From your post above we must take it that you have investigated what Brown/Terman have to say on this subject, and can prove them wrong. If you wish your statements to be believed above theirs, you will need to show your work. Immortality awaits.

.07 DB might be gain, but I somehow get the feeling that I would never
notice it on my HF rig. What would that gain represent on a 1000
watts? I don't know the formula, just the generalization that 3 db =
double power.

4468. Top Hat on J-Pole ... was Helical wound slim jim?

Newsgroup: rec.radio.amateur.antenna
Date: 2005-03-29 20:09:25 UTC
From: Buck <iam@this.site>
Message-ID: <j7dj415q704btopv5tu4r597rlaceqvibl@4ax.com>
Source record: 80012

In some situations it is better to have a 'shortened' antenna than the absolute last tiniest fraction of a db. I realize a cap hat can reduce the size of a vertical with reasonably low loss, I am wondering if it would do as well with the J-Pole?

For example, a quarter wave matching network for the J-Pole would be whatever works best, be it original design or some form of balun, but the 1/2 wave vertical might be reduced in size by forming a capacity hat above it.

How well would that work for shortening a J-Pole? would it be better to use a shortened 1/2 wave dipole or would the J-Pole design be better?

Buck

Source record: 80014

I should also mention that the requirements for an insulator depend heavily on the application. An insulator which results in a lot of loss when a large electric field is present might produce negligible loss when the field is weak. For example, an insulator at the base of a very short or half wavelength high vertical, or at the end of a dipole, has to be pretty good in order to minimize loss, because the electric field is high at those points. On the other hand, a poor quality insulator is just fine at the base of a quarter wave high vertical or the center of a half wave dipole, since the electric field is low at those points.

Roy Lewallen, W7EL

Yanno?
I took the dimensions of the "Ark of the Covenant", as detailed in the bible, and extrapolated them to dimensions I could use in the construction of an "EH Antenna!" (it is held together by prayer and I don't know if this is affecting the directivity or not), I constructed the antenna, attached it to a hard hat (again, it is held to the hat by prayer and that could be affecting performance) and placed it on my head...
I now think I am on the verge of a break-through in communications with Heaven (cutting out the middle man, i.e. priest, the savings in tithes alone could be a miracle!--possibly leading to a 1db+ gain in money in my bank account, Praise the LORD!)
At this point, I AM HEARING VOICES! My exuberance is nothing short of spiritual!
Conditions are a bit down right now, when they improve, I will request a QSL card and post it here as confirmation...

How better indeed? As I remember, it was Dr. Best's assertion
that the source always provided the extra energy during construc-
tive interference (no matter how far away the source might be).
I, OTOH, tend to believe "Optics", by Hecht where he asserts
that there must always be an energy balance between constructive
interference and destructive interference (as demonstrated by
the radiation pattern of an antenna).

It's certainly correct in almost any instance to say that the source of energy provides the energy. Not necessarily so of other points in space. And only rarely do we find any "extra" energy in physical systems. ;-)

Art, I once has a fuzz-phrase card with ten words in each
of three columns. One picked three numbers at random and
looked up the words for inclusion in a memo or paper. One
possibility might be "integrated quantitized phenomenon".
I suspect Richard C. has some rather sophisticated fuzz-
phrase software at his disposal. :-)

4488. Palomar noise bridge

Newsgroup: rec.radio.amateur.antenna
Date: 2005-03-30 00:48:17 UTC
From: Jaggy Taggy <outhouse@midcoast.com>
Message-ID: <BE6F61BF.7319%outhouse@midcoast.com>
Source record: 79883

I recently got myself a noise bridge to do some quantitative measurements on my antennas.
Lets say I am a bit disappointed. The small dials of the unit make all my antennas to appear very similar indeed and I am wondering if the unit is broken (not according to the test I did with a known load) or if I am expecting way too much.

What do real people use to do impedance measurements on their antennas (and please do not suggest anything from MFJ).

Ahhh! Then there must also be a transmitter in the collar to "answer back" to the stationary transmitter? If so, maybe the thing works on the amount of time calculated for the signal to travel round trip. A radar mile (2 miles round trip) is about 12 microseconds, if I recall. Rountrip at 90 feet would be something like 183 nanoseconds. If THIS is how the unit works, running a kilowatt wouldn't make a difference. It would require changing the interval time that the transmitter waits for check-back. Maybe I'm making this too complicated ;) It must be simpler and then I would think they would use something other than 17 KHz....interesteing!!

I'd like to hear more about MFJ, and why you dont want to hear more about them. I was thinking that they were a pretty good way of measuring impedance.

Cecil,
What ever happened turned out O.K.
Looks like he left and took a holiday
When he comes back, if he ever does,. maybe he
will be a bit more mellow to his fellow man.
. His degree is in the Arts but I think he saw to much
of Shakespeare and not enough of Gilbert and Sullivan,
which is probably why he has one hand on his knife at all times
I suspect he does have a 'Fuzz" card but it is in Elizabethan
which, being dated, fits in quite well for someone used to
appearing from 'stage left' in antenna discussions
Art

Sorry Richard. I never refer to sources. Except perhaps Ohm.
There's no way of guaranteeing reliability. I work things out for
myself so you'll just have to take my word for it.

I have a remarkably small book library. Although I did buy a
second-hand copy of Terman in 1947 which I still occasionally browse
through when I'm running short of ideas. He's most comprehensive.
Which accounts for his continued popularity. But he's not God. Anyone
who has actually tried to use him will know that.

I do have volumes from A to S of notes accumulated over the last 45
years. But some papers are about telescope making which was a hobby of
mine before our night skies became polluted with vapour trails and
other fumes. And some wicked kids stole my camera.

Reg.

Well, if it's okay for the mast to be next to your house -- why not
just set the mast on the ground in a shallow hole, and support it with
your roof overhang, about 10 or 12 feet up?

You might also check the Radio Shack web site -- they have all kinds
of inexpensive brackets, guys and paraphernalia for tv-type masts,
which may work with your fiberglas mast.

Hi Tom,

Guessing and supposing seem to be de Rigueur. Let's look at it
through deconstruction (the convolutions of language used here are to
thin out the shallow end of the grammatical pool) and let me ask:
"Considering your reaction, Art's stimulus by which I made my
suggestion, and the comment itself: does all this maintain a
consistent, internal logic?"

If I were to deconstruct further, I would offer the query:
"How current is semi?"

If we reach back beyond the currency of semi (say 3 or more decades);
then I would have offered Art:
"Keep a tight ass hole."
and it would have still come from the same culture.

Now, at the risk of having to "explain" to a generation that demands
facts and references, and then shows so little inclination to actually
apply them (this does not mean you by the way as you have been
adventurous enough to probably have made connections anyway); then my
short answer would be:
"You've guessed wrong." (which is a far more commonplace outcome
by virtue of this preponderance of guessing, presuming, and supposing
instead of testing, analyzing, and examining).

5 points to the one who can name the source to the ancient (nearly 40 year old) quote offered. 5 extra points if you can provide the context (fictional character) who employs it. And 10 points bonus if you can name (fictional character) who it is applied to.

I agree with Jerry. Why not use an MFJ. I have two of their oldest units one for HF and one VHF, the models 207 & 208. Bought mine a long time before he put the to measuring devices together. They measure the resonant freq. and that is what you want to know right? Mine have worked fine for years and still do. His newer instruments are just great. Wish I could justify buying the new MFJ-259B. I had the chance to play with one and it is terrific. If you can't determin everything about your antenna with that, well, you are just a lost soul in a techie world. Friends still will borrow one or the other of my ancient units to check their new construction or to find how far off their antennas have become from the original design. MFJ makes affordable, accurate, devices for Hams and as long as Martin F. Jue is running the place they allways will.

Hi Uwe,

The Cadillac of Bridges is the General Radio 1606-A. However, it
requires you to have a source and detector. It is only a Bridge, but
it is a precision Bridge. The circuit is quite simple, but its triple
shielding and isolation are old-world craftsmanship. These things
sold at a price equivalent to 6 months wage for a bench tech. 6
months wages currently will buy you equipment that could do what was
only possible in a standards lab back then - but this is still in the
region of 5 figures.

You will need a stable source capable of 1 to 10mW power. You will
need a well shielded communications receiver to act as a detector.
You will also need a steady hand to balance the bridge (which may be
part of your problem with the noise bridge). Nulls are often more
than 100 dB deep. If you lack sufficient shielding for the detector,
this will degrade the nulls considerably. If you lack stability, you
will never find the null.

The MFJs of the world are quick and dirty, but when they reach their
limits you can only guess because they will as easily feed you a bogus
reading when they are out to lunch. The GR 1606 has limits too, but
they are obvious by dial indication and a top end of 60MHz usage (a
more practical top end, however, is 30MHz).

Richard

As you know, I built that slotted line that works fairly well for load
impedance measurements at 2 meters, and can be used at 100 MHz for FM

antenna work. But, it is big and ugly. I do like the concept MFJ uses even though the results are surely less accurate than a good bridge. If I get an urge to include a HF antenna or other device whose impedance I want to determine, I might buy a MFJ. But, if a decent bridge ever becomes available at one of the HAM swap meets I'll sure pick up anything thats affordable.
I am impressed that computer programs seem to have made impedance *measurement* unnecessary to most HAMS. I sure wish I was enough smarter to be able to manipulate the computer so I could get confidant about computer program results. That really impresses me when I read about how accurately antenna impedance can be predicted for various changes in parameters.

When you guys arent argueing about stuff I cant understand, I sure learn alot from this Antenna Group.

Thanks
Jerry

Hi Jerry,

Imagine how ugly it would be for 20M. You could use yours there too,
but you would have to study how to do what is called "load shifting."
Conceptually it is quite simple, but as you have learned, the art of
construction is where the accuracy is.

> I do like the concept MFJ uses
>even though the results are surely less accurate than a good bridge.

There are so many ways to lose accuracy that you should look at the
point spread. MFJ (and the other manufacturers) will probably suit
90% of users' expectations.

Affordable generally runs in the neighborhood of $300. Myself, I
would invest in a swept frequency system that does vector analysis and
build heads that perform the SWR determination. This is
software/hardware at its best. Flexibility is the hallmark of an
instrument that will be kept being used.

4508. 31 Mix Beads RFI Suppression (Ignition)?

Newsgroup: rec.radio.amateur.antenna
Date: 2005-03-30 12:33:36 UTC
From: hasan schiers <schiers@netins.net>
Message-ID: <d2e6bi$p6h$1@news.netins.net>
Source record: 79903

I see 31 Mix snap-on beads listed by DXEngineering as effective in reducing ignition noise by placing them on ignition wires. (0.275 inches)

I have several questions about their application for ignition wires:

1. Where along the wire should they be placed (at the plug, at the distributor, middle of wire)?

2. Should they be stacked next to each other for better effect (series butted up against one another) and if so, how many, and again, where along the wire?

3. How many should be used and as above, how should they be "clustered"?

They come in packs of 10 and since I have a For Taurus ('95) 3.0 V6, I have 6 wires to deal with. 2 packs would yield 20 chokes, for example, and perhaps a silly way to look at it would be to put one at each end of each wire and one in the middle of each wire, using 3 per wire or 18 of the 20 available.

4. Are these likely to be significant help on either HF or VHF?

5. Can anyone recommend a really good set of ignition wires for best RFI suppression?

(and yes, I'm aware of the fuel pump noise problem...but I'm concentrating on ignition noise at the moment)

TIA

Using scientific texts and methods rather than a thesaurus and fictional references to try to make your points here would serve you (and the rest of us) better.

Or you might wish to move to alt.english.usage, and see if those folks are impressed.

Hmm, I'd say about 61 years +-1 on the quote, and I couldn't guess who
used it 40 years ago.

And blunt is now a drug reference if you haven't kept up.

So who was it that recycled the combat advice?

I suspect that your statement above that you never refer to sources doesn't mean that all of your considerable knowledge is the result of your original investigations. Even your countryman Stephen Hawking credits his sources when he writes of scientific topics.

Terman's (Brown's) statements about the elevation patterns of loaded verticals have been proven empirically by MW radiators for 70 years or more. There is nothing to argue about, and certainly no reason to take the word of anyone not willing to show conclusively how this concept is invalid. One's word is insufficient -- even if it comes from you and/or Richard Clark.

Richard

Your thoughts on sweep frequency for impedance measurement is very
interesting. If I could figure out a way to build the "sensors" I'd
probably build a sweep system for 2 meters. Although I could handle
building a sweep frequency generator, I wouldnt know how to convert the
"incident and reflected" to an impedance.

I suspect that, if sweep frequency impedance measurements was simple enough for Me to do, someone would already have done it and published in one of the HAM magazines.

Note that this is an admonition against getting drunk,
not against drinking wine. I just saw something on the
history channel that implied that Jesus' motto may have
been, "Eat, drink, and make Mary." Information comes to
us from some ancient cave tablets that Jesus was married
to Mary Magdeline (sp?) and fathered a daughter named Sarah
who fled to Egypt and later married into European royalty.
It was the jealous apostles who later made Mary M. out
to be a lady of ill repute. The Holy Grail is supposed
to be Jesus' direct blood line.

Hi Jerry,

Quite simple. Radio Shack sells SWR meters for 2M so you can take a
lead for the sensors from there.

>Although I could handle
>building a sweep frequency generator, I wouldnt know how to convert the

Software would do that.

I'm sure that's already been done, at least in the ads in back. I am
NOT discussing what might be, but what has been done. There is a kit,
or kit design on the net, it's been mentioned here, I just haven't
rummaged up the link yet.

Cecil

I've always ignored the use of twin lead for impedance measurement. But,
it makes sense. I may try building something like that, just for fun.

I certainly havent thought this "twin lead" line thru but it seems that
one could be easily built from a length of PVC pipe with wires attached to
its sides.
This seems too easy and relatively accurate for "home in the garage" use.
I'd bet I can find some info on the Internet for FM and TV frequency use.
Thanks for jogging my mind.

I have one of the MFJ "atomic" clocks in my basement shack (in New York) It will not pick up the WWV signal in the basement, but does fine when upstairs and placed in a vertical position. There is no external antenna connector---that would make things too easy. Is there an accepted way to connect an external antenna? Any experience with external antennas on these things? (This should be a very common problem!)

I have not taken it apart yet -- sometimes such things are easier to take apart than to put back together. I am quite willing to take it apart if there is a good reason for doing so.

I recently purchased an old crank-up motor driven 60 foot tower that I would hope someone could id for me. The motor belt drives a gearbox, which turns the cable pulley. It has a approximately 1 foot by 18 inch control box which has two high current relays and two glass contained relays. The glass-contained relays are in old 8 pin tube sockets.

The tower, itself, is in good shape. I would like to re-build the control circuits and out the tower in service. Any information anyone can give me on this tower will be greatly appreciated. See at www.winlyn.us/tower.jpg.

Same as above but with a field strength indicator? Just might work if I
use a 4-digit DVM and a diode.

> 3. Find the Vf (as you put it) by derivation against a wire model
> (through the difference in lengths of bare wire model resonance to
> real wire resonance);

That would seem to work but I'd expect to still have the flat curves
because of the coax losses. I'm starting to think I should go to a
lower frequency band like 40 or 80M to reduce the problems with the
coax. And to reduce the errors in cutting-to-length.

> 4. Use the new EZNEC which allows you to employ insulation over wire
> and adjusting the thickness to conform with results found
> experimentally with real wire at actual length;

. . . all I gotta do is DO that! "The loop has been closed."

> 5. Assign these insulation properties to all future designs in the
> modeler.

I've been using Nec Win Plus which is OK but it doesn't have the the
ability to handle velocity factors like EZNEC 4.0 can.

I don't have a big problem with scaling antenna dimensions to adjust for the Vf because I physically model antennas with CAD first to get the locations of the wire end points in 3D space. Which I can quickly and easily load into NWP. The CAD program does all the tedious trig for me. When I have a bare-wire model which "works" in NWP I can rescale the physical model by 0.98 or 0.95 or whatever the Vf might be to get a "close enough" fully dimensioned antenna design. But I still need to find the Vf experimentally and we're back to square one. You fed me some thinking fodder, I'll try a few things per above and get there one way or another.

Tnx.

Reg, G4FGQ wrote:
"No it doesn`t! (Thus an antenna for which H=0.45 lambda can by suitable top loading be made to have a field distribution in the vertical plane of H=0.6 lambda.)"

Reg is right. Between two antennas there will always be differences. But, as Richard Clark might say, "Does it make a Db of difference?" One dB can easily be lost in measurement error.

Top loading has been around since at least 1909 when it was patented by Simon Eisenstein of Kiev. Russia. See Fig 9-24 on page 9-17 of ON4UN`s "Loe-Band DXing". Eisenstein shows current distribution on his patent application. He gets the base current up as it might be in a full height antenna.

I would believe what Terman wrote because I`ve never been able to disprove anything he wrote. Now I look for my error in logic when something of Terman`s seems wrong.

ON4UN says on page 9-29 of his 1994 edition of the Low-Band DXing book: "Over sea-water the 5/8 wave has lost 0.8 dB of its gain already, the 1/4-wave only 0.4 dB." (It`s less than one dB).

Even a disappearingly small radiator produces radiation less than 1/2 dB weaker than a 1/2-wave dipole, or a 1/4-wave vertical. In lossless antennas, the only difference in radiated signal between the full length antenna and a too-short antenna comes from the slight difference in their patterns.

Short antennas have efficiency problems because they have low radiation resistances. This low radiation reaistance goes not compare as well with a given loss resistance as does the higher radiation resistance of the full size antenna. However, great care can be taken with the too-short antenna to minimize its loss resistance and get good efficiency.

You have only to consult the "ARRL Antenna Book" and compare a short continusously loaded vertical`s performance with that of a full-size 1/4-wave vertical. In my 19th edition it`s on page 5-25:
"Fig 46-Helically wound ground-plane vertical. Performance from this type of antenna is comparable to that of many full-size 1/4 vertical antennas."

In 1949, I worked in a transmitting plant where two stations, KPRC, 950 KHz, and KXYZ, 1320 KHz, shared the same transmittinng tower. Both stations had identical RCA 5-C, 5 KW transmitters. Regional coverage was almost identical despite many more degrees in the tower at 1320 KHz than at 950 KHz.

One of the operators at the stations was a ham. He was J.L. Davis, W5LIT. J.L. had a new 1949 Ford with a cane pole bolted to the rear bumper. The pole was wound nearly end to end with enameled wire to serve as antenna for his mobile ham rig. He had no top hat at the tip of his antenna, so sometimes when he was talking a high voltsage corona discharge would plume from the top of his antenna. Very impressive though no help to his QSO..

Bill Orr writes on page 78 of "Vertical Antennas":
"A helix length of about .05 wavelength or more provides good results as a substitute for a full size quarter wavelength vertical antenna."

It worked for W5LIT.

Best regards, Richard Harrison, KB5WZI

Hi Bill, if you do open the receiver, I would be very careful how much signal you apply, as the front end could be extremely sensitive and might easily be destroyed by applying an external antenna directly. You could try running an insulated antenna wire from some area that has reception, and strip the insulation to fasten to the back of the clock (without opening the back).

If that doesn't work, here's a new hi-tech digital clock that will:

Hi Albert,

This could be an ID modulation to serve the receiver's logic. In
other words, correction is based upon both signal strength AND
modulation.

Thus the received signal strength has to fall to a certain level that
is still above noise level (not complete drop-off) to insure that
corrections are not applied due to power failure at the transmitter
(and to allow registration at power-up).

>VLF is used because the signal penetrates the ground better,

This was what I described as the subterranean communications channel
used in the trenches of WWI. I would still suggest a power boost over
building a ground dipole. The design of the amp is trivial, and kits
are available to do the job for less than $20.

I still remember a demonstration of transmission line phenomena given by Dick Silberstein, W0YBF, at the Denver Radio Club more than 30 years ago. He had made a "slotted line" (more accurately a trough line) from a wire tightly suspended in the "V" of a piece of angle aluminum or steel. It worked very well. It was pretty large -- I believe the frequency he used was around 50 MHz. You could use a smaller piece of angle material or suspend it deeper in the valley for a higher frequency.

Until you achieve relief (you haven't described why you want to do
this).

>4. Are these likely to be significant help on either HF or VHF?

By the presumption of this indicating a receiver problem with HF or
VHF, I would offer that most (modern) cars do not display such
problems. You could be chasing the wrong solution. However, at the
bottom line, they could help.

>5. Can anyone recommend a really good set of ignition wires for best RFI
>suppression?

Standard resistive wires. It sounds like you substituted straight
wires for the factory set when they wore out. That is generally a
poor choice for two reasons. One (presumably) is due to ignition
interference with communications. The other is lowered fuel economy
and power.

The application of ferrites to straight wires is introducing resistive
loss into the ignition current path. This is normally the job of
resistive wire. Introducing such loss is actually a boon. The loss
retards spark extinction (means that the spark will burn longer with a
resistance in the path). Longer burn time means more complete
ignition. This also means that the longer burn time equates to fewer
HF spurious products. This is called win-win.

Bosch, and at least one other company whose name I've forgotten, used to make a solid wire ignition cable that was coiled internally into a very long choke. I used them 15 years ago on one of my vehicles that had a noisy ignition system, and they were fairly effective, better than resistor wires were on that car. I am not sure if they are still made, but asking at your FLAPS should give you a quick answer.

tom
K0TAR

Oh, FLAPS is short for Friendly Local Auto Parts Store.

Excellant choice (add a filter cap too with resistive load for
averaging).

>> 3. Find the Vf (as you put it) by derivation against a wire model
>> (through the difference in lengths of bare wire model resonance to
>> real wire resonance);
>
>That would seem to work but I'd expect to still have the flat curves
>because of the coax losses.

Hi Brian,

Actually, by using the FSM you entirely remove the transmission line
as disturbance to accurate response readings. Those come from the
external reading which interprets all power being applied AT the
antenna junction. However, it imposes upon you that you be scrupulous
about achieving the same drive levels at all the intermediate
frequencies across the swept band. If you do that, then the
transmission line characteristics for the drive going up to the
antenna junction fall out too.

Careful drive monitoring, and careful response monitoring render the
transmission line transparent to the measurement. Thus response/drive
is the antenna characteristic. Define one point's SWR, and you can
cast that into the suite of readings for a swept SWR curve. Take care
in that "one" SWR determination to anticipate the SWR lowering effect
of transmission line loss.

Then you do the same thing in software, and tailor the characteristic
insulation thickness to match your measurements. Having achieved
that, then you have your standard insulation. This does not give you
Vf until you then remove that virtual insulation and find the native,
bare wire resonance. This last step is satisfying (it answers your
question as to Vf), but the step before is more useful because you can
model other antennas from that standard.

That trough configuration is probably more practical than the copper tube coax thing I made. I dont have any current interest in 50 MHz impedance measurement. But, I'll sure consider that "angle trough" method for any low cost tools for impedance measurements. I realize now that a slotted line even for 137 MHz is too large to have around in my garage. It requires too much room to set up the equipment. It is kinda interesting to consider something made from PVC so it is "disposable". I dont know how I'd handle the transitions to and from the coax. But, it seems like a guy could use a couple 4:1 baluns to get from 50 ohm coax to 200 ohm twin lead. I'm pretty sure I could find a couple long lengths of copper wire or tube that I could attach along the sides of some 1 inch PVC to make a 200 ohm line. That would be about 20 feet long for 6 meters. Wow, thats big.

Maybe I should just get back to learning EZNEC. You guys actually get good impedance predictions for almost any antenna.

If the relays need replacing, you might consider replacing them with "solid state relays." A led optoisolator triggers a triac device to control power to the load, I have used them in the construction of 13.8V linears with excellent results, suspect they would work well for this application too. They are commonly available for ?-100 amps @ 220V, a search of the web should provide you with ample sources...

I, for one, am not picking on truckers. They have the SAME options the other licensed hams have: study for and EARN the privilege of using radio. They are, like every other citizen, are permitted by law, to operate a CB radio with 40 channels and 4 watts. On any given day, most of those channels will be reasonably quiet except for a very few. He may use any of those channels for both finding loads/drop offs, or as recreation. He may NOT encroach on other frequencies at will. If he does, he is liable for fines and even being fired by his company. If you don't believe it, just email rholling@fcc.gov and ASK! MANY trucking companies have been made aware of the 28 MHZ incursions and have been VERY cooperative with FCC in stopping their drivers from using "extree" channels--even going so far as to FIRE one or more for it.

As for Amateur Radio, the bottom line reason for its existence IS emergency communications. It is the number 1 backup to existing communications services, and most
state and local EOC (Emergency Operations Coordinators) would not be caught DEAD without an Amateur Radio presence in their planning. It even receives Homeland Security funding for equipment and training. It also provides a measure of innovation in communications technology and continues to evolve in this manner. THAT , not "hobby" communications, is the reason for its continuing existence. The "hobby" aspect is what leads to experimentation, invention, and communications innovation.

Your assertions as to the basis and purpose for Amateur Radio show complete ignorance of the applications of communications technology and come from an obvious "CB Radio" mentality. Perhaps, it would be best if you stuck to truck driving since your knowledge of communications is most surely contained within the circumference of your steering wheel.

This is the greatest thing since sliced bread.

I've built one for ~$250.00. Here's a photo taken during construction
and checkout:

http://www.qsl.net/n7ws/ANA_1.jpg (350K)

Currently it's limited to 60 MHz although variants are in the works to
increase this. Another minor limitation is that the software is
DOS-based although Windows software is under development by other
users. Xp users, like me, have a couple of hoops to jump through to
access the parallel port but it's no big deal.

The accuracy, however, is lab quality and is comparable to commercial
network analyzers costing tens to hundreds of $K like I used to use,
although it's achieved at the expense of measurement speed.

Also see:

http://groups.yahoo.com/group/N2PK-VNA/

A higher cost alternative with much reduced dynamic range is here:

http://radio.tentec.com/Amateur/vna

That's just it.....you will never know it Uh, until you get the
registered letter from Gettysburg, PA. "Dear sir, Evidence before the
Commission that you have been transmitting on 28.xxx MHZ. Please be advised
that such operation requires an FCC license. Penalties may be asessed of up
to $10,000 per occurance, or a year in jail.
You are requested to call me,....., at 717-338-XXXX to discuss
this matter".

Then go ahead and ignore the letter.

(they don't HAVE to have your tag #)

Thanks Jack, thats a great clock.. All my buddies will be getting one of
their own soon. I already have mine.

I was thinking that Bill might be able to get his other clock to pick up
WWV by the same method you suggested. But, I was wondering if he could

tolerate having a few turns of the wire from outside wrapped around the clock on the way to a ground connection in the room.

OH! So "evil" is what YOU say it is, right? Ergo, disobeying established
law--namely Title 47 US Code--is not "evil" according to YOU, right.

That US Code is crafted to protect ALL persons, including those who are
ignorant and untrained about radio, from massive interference. So "evil" is
the legal, licensed, well-established laws governing radio and the
unlicensed, trashing, and non-essential over-powered, over-modulated,
over-tweek and peaked chicken band radios are "good", right?

Yeah, Shurrrrrrrrrrr' it is. Shurrrrr' it is!

That's the first of the five "fundamental purposes" of amateur radio,
as cited in the FCC regulations (which enact the stated will of
Congress, at least in principal).

> The "hobby" aspect is what leads to experimentation,
>invention, and communications innovation.

That's cited as the second fundamental purpose. Expanding the number
of "trained operators, technicians, and electronics experts", and
promoting international goodwill are also cited as justifications.

Congress and the FCC acknowledge that amateur radio provides a value
to society, independent of any direct delivery of cash revenue to the
Government.

> book: "Over sea-water the 5/8 wave has lost 0.8 dB of its gain already,
> the 1/4-wave only 0.4 dB." (It`s less than one dB).

I think you should question that conclusion. Sea water (or any path of fixed parameters) attenuates every groundwave by the same decibel amount for the same path, conditions, and frequency. For example, using the FCC curves for groundwave propagation from a radiator with 1 kW of power and 120 1/4-wave radials, over a seawater (only) path at 1MHz...

- a 1/4-wave vertical produces a field of 190 mV/m at 1 mile,
and 85 mV/m at 2 miles.
- a 5/8-wave vertical produces a field of 274 mV/m at 1 mile,
and 137 mV/m at 2 miles.

This is as expected. Doubling the distance reduces field strength by 6 dB in each case. The absolute value of the groundwave signal has no bearing on the percentage of it that is lost as it propagates.

> Even a disappearingly small radiator produces radiation less than 1/2 dB
> weaker than a 1/2-wave dipole, or a 1/4-wave vertical. In lossless
> antennas, the only difference in radiated signal between the full length
> antenna and a too-short antenna comes from the slight difference in
> their patterns.

The difference in peak gain between an isotropic radiator and a reference dipole in free space is 2.15 dB. Practical antennas in real-world applications can show greater than 0.5 dB losses for shortened radiators. In my example above, the 1/4-wave radiator would need about 2 kW of input power to produce the same field as the 5/8-wave radiator with 1 kW, over the same path -- which is a 3 dB ratio.

> In 1949, I worked in a transmitting plant where two stations, KPRC, 950
> KHz, and KXYZ, 1320 KHz, shared the same transmittinng tower. Both
> stations had identical RCA 5-C, 5 KW transmitters. Regional coverage was
> almost identical despite many more degrees in the tower at 1320 KHz than
> at 950 KHz.

If the tower was 90 degrees at 950 kHz it would have been 125 degrees at 1320 kHz. The FCC efficiency for 90 degree towers is 190 mV/m at 1 mile for 1 kW, and about 210 mV/m for 125 degree radiators. So the 1320 kHz signal was launched with a greater groundwave, but that advantage would be lost as the signal propagated over whatever the ground conditions are for the path (higher freqs have greater losses). Using the FCC curves and a conductivity of 8 mS/m, the 5 mV/m contour should be about 35.5 miles away for the 5kW

950 kHz station, and about 27.5 miles away for the 5kW 1320 kHz station.
But close in probably few would know the difference.

> Bill Orr writes on page 78 of "Vertical Antennas":
> "A helix length of about .05 wavelength or more provides good results
> as a substitute for a full size quarter wavelength vertical antenna."

Was 0.05 lambda the pitch of the helix? If so, how many turns? How were
the two installed? How were the antennas oriented, and In which direction
from the antennas was he comparing them?

+ + +

And thanks for some serious comments on this subject.

Leonard Martin wrote:
"But how do I create a base for this thing?"

Best source of information is usually the supplier of the "thing". He has incentive as it helps sales to show you, the customer, how to use the product to your satisfaction. Telescoping fiberglass masts especially need detailed instructions due to novelty and complexity.Contact the manufacturer if the seller won`t help. He may respond to an e-mail. They should show you how to make and place good concrete.

Rohn Towers, for example, has published books on how to choose and use their products.

The all-purpose source of antenna information, "The ARRL Antenna Book" has in my 19th edition, tower bases on page 22-12. Unfortunately they don`t tell you how to make good concrete. You need a mix rich in cement (a 6-sack mix) and nearly as dry as you can mix it and be sure that it`s just damp enough for all the cement to react sooner or later. You place concrete, rather than pour it. It`s worth reading the book anyway.

Best regards, Richard Harrison, KB5WZI

I simply cannot resist:

"Antennas will get you through times of no propagation better than
propagation will get you through times of no antennas."

I'll admit that I've lost the plot to this thread. Although, I've
picked up some interesting pointers on antenna design with respect to
electrical length. I really need to pick up a copy of the Terman book,
if only to read up on some of the references I've seen here.

At least it will give me a reason to use my erstwhile maths skills for
good, instead of for evil.

Hi OM,

I will concede the post of Beauty Queen to your overwhelming lead.
Tears will stain my pillow tonight. :-(

However much you may pine away for technical discussion, you balance
that with the relish to gust on with personalities. Clearly your
contest but no points for content nor style. Careful, there are
others eyeing that crown you seek.

I posed a question about pop music and antennas, both, given you have
abandoned the topic long ago. This in itself merely underlines how
inconsequential its outcome was. The vacuum of discussion along any
of those lines portends more banal gossip. I shouldn't await any
surprising development in your writing skills; but I'm an optimist and
look forward to that slight glimmer of talent that goes beyond the
swim suit competition.

If he obeys the rules of the road as he seems to suggest he does of the FCC or shall we say a considerable lack thereof, then he won't be making deliveries long. His road will soon come to an end via his own severe injuries to cause loss of job or perhaps death if not the loss of license - beforehand. I'd still like to know how the one reply to "my" post - plonking him, suggested he was only trying to help..... Again I ask, help? WHO? Of course, that "supporter" - was also plonked. I'm not picking on anyone or group, but his logic WAS flawed. He feels because truckers do such service, they deserve to have their way. OK... what about the "bad" cops? They do a good job - usually, til they bend the rules! We wouldn't like them either. Same with politicians and so on. Bad ones don't do anyone any justice in the end, no matter how much good they've done in the start. One doesn't displace the other. Your "good deeds" do not or SHOULD NOT give you leverage to do

evil even if in your eyes, disobeying those darned FCC Rules. IF we ALL disobeyed the laws, then this country will be back to the prehistoric ages, everyone killing everyone to do their own bidding. Everyone will have to tote guns to protect themselves from everyone. Radio and TV would be total chaos... No more could you listen to or watch a favorite program, as the pirates would be bombarding them with illegal signals or splatter from such. Without rules/laws for radio, even CB/Ham, it will be useless for all, even those who intend to try to destroy it for their own good. But, they're too short sighted to see that.

Richard Fry wrote:
"Was the 0.05 lambda the pitch of the helix? If so, how many turns?"

I`ll quote Bill Orr for accuracy:
"Resonance can be established at a given frequency by the use of a short, helically-wound element (Fig. 14). Treated bamboo poles (J L`s choice), PVC plastic tubing, or fiberglass quad antenna spreaders can be used as a form on which to wind the helix. Diameter for the helix must be small in relation to length and a practical design makes use of a one inch (25,4 mm) winding form. A helix length of about .05 wavelength or more provides good results as a substitute for a full-size quarter wavelength vertical antenna.

The amount of wire required for the winding depends upon helix length and pitch (turns per inch). In general, a half-wavelength of no. 14 Formvar-coated wire is spirally wrapped on the form, with spacing approximately equal to the wire diameter. This amount of wire approximates a auarter-wave resonance"

There are helical antennas of two types. The "axial mode" invented by John D. Kraus which radiates in the direction of the coil axis and the "normal mode" helical antenna which radiates in directions perpendicular to the coil axis, as does a short straight wire. Carried to extremes, the pitch could go to zero,in which case the coil becomes a loop, or the coil is stretched out to a straight wire. The helical antenna referred to by Orr, is the normal-node helical antenna.

While the axial-mode helix is a broad-band antenna, the normal-mode helix is a high-Q antenna and has restricted bandwidth. Orr has something to say about the high-Q normal-mode helix:
"In order to prevent any high voltage discharge, a 12-ibch (30 cm) diameter wire top hat is attached to the helix. Antenna resonance can be adjusted by varying the size of the hat, or by adding a small extra inductance at the base of the antenna."

There was also a question about directive gain which often brings a surprised response. Terman is my source for directive gain. On page 871 of his 1955 edition of "Electronic and Radio Engineering" he gives the directive gain, not in decibles, of 1.5 for the directive gain of the elementary doublet. It is not isotropic. It is however infinitesimally short. In the same Table 23-1, Terman gives the gain of the full half-wave dipole as 1.64. There is precious little difference in directivity or gain, which are two sides of the same coin, more or less. Maybe Art can make a high-gain antenna of very short elements if he can just get them to take a lot of current and not waste much to loss

Best regards, Richard Harrison, KB5WZI

Hi Mike,

No, that was abandoned long ago and an attempt to draw it back with a
novel topic of surface phonon polariton efficiency hits on antennas
was similarly abandoned as too easy (? who can tell what will lead to
a 600 entry thread?). However, the question:
"What does Do Wa Diddy mean?"
predictably blew a fuse.

Thanks. Maybe I'll model that in NEC and see what it shows. Or did you do that already?

> While the axial-mode helix is a broad-band antenna, the normal-mode
> helix is a high-Q antenna and has restricted bandwidth.

The VSWR bandwidth of a normal-mode helix depends on its design. Below is a link to one that, with branch feed, has a bandwidth of 12 MHz in the FM broadcast band (see the text at the bottom of the first column of p 1).

http://www.dielectric.com/broadcast/brochures/DCR-M.pdf

The 1.5 and 1.64 are multipliers. Multiplying power by 1.64X is a gain of 2.15dBi, that is, 10*log(1.64).

Evil is easy to define, some guidelines would be:
--an evil person would lie for their own personal gain.
--an evil person would deprive another of their property.
--an evil person would deprive another of their means to earn a living.
--an evil peson would deprive another of their pursuit of happiness.
--an evil person would enjoy bodily harming another.
--an evil person would deprive another of his life.
--an evil person is generally sociopathic, and generally has no consideration for others, other than if it is in their best interests to do so.
...get the picture?

Evil leanings can be overcome with the practice of a simple ideal--do onto others as you would have them do onto you...

In other words, evil people generally have a disregard to others lives, hopes, plans, needs, wants, etc., indeed, a general disregard to another life in general, other than there own and, possibly immediate family (at best.)

However, generally people are in danger of being evil if they even hint that it is difficult to define evil--if you don't know it when you see it--there is probably a good reason why! It has been my experience that evil people are the least likely to recognize they are evil; a read of any good book on serial killers or child molesters will confirm this to you.

Hi Albert,

Given the features you've imputed to the design, transmitter drop out
(loss of AC power) would be indistinguishable from puppy border
crossings.

Or, yes, it could be signal strength alone (still argues for a simple
Amp any 'splanation considered).

Part Deux of the mysteries of the VLF is looked forward to.

Too many DO think that way. Once on I-80, I saw an event -I hesitate to call it an accident, because there was no real damage - where a truck slid sideways and blocked the road during a bad snowstorm. The truck blocked the road, so we were all stuck. Listening to the CB, I heard the story morph from what actually happened into some "4 wheeler" passed the truck and cut him off, causing him to lose control. After 10 minutes, *that* became the "official" story. Too bad that isn't what actually happened.

Always blameless, never wrong.

Hi Mike,

At least three of us have access to Bailey's "TV and other Receiving
Antennas." It is exceptionally readable and covers propagation beyond
the usual glazed-eyes-in-the-headlights attention to TOA.

3 copies available at:
http://www.alibris.com/
but flabbergasts me that the burden runs from $30 to $187 for this
volume printed in 1950. Or try:
http://www.bookfinder.com/search/?author=&title=TV+and+other+Receiving+Antennas&submit=Beg
in+Search&new_used=*&currency=USD&mode=basic&st=sr&ac=qr

Amazon is usually quite useless for these older titles.

And while your trucker friends are screaming "HOW "BOUCHA THAR, YUH GOTTA AN
OLE COPY THAR, WE TRYIN' THAR, MERCY SAKES THAR"
And if the 27 Megs band is dead? Silence..except for the mishmash of
truckers jamming each other with their "leenyars".

While those hams just move down to 24, 21, 18, 10, 7,
5, 3.8 MHZ and pass the traffic for EOC and FEMA or MARS.

CB radio is a hodgepodge of mishmash thrown together, peeked and tweeked,
squeaked and beeped ,splattering trash that couldn't effectively move radio
traffic if it smacked them in the face! They wouldn't know what to do with
it if they tried. Ha! They'd just get into a king of the hill battle trying
to key over one another!

Traffic handling in a national emergency is not just a matter of having
'them thar reddios with lotsa 'swang and far in th' war (fire in the wire),
but a matter of training and discipline. Without experience in precedence,
cataloging,
knowing what messages must be handled first, That, sir, those hams have in

abundance. It is why there are training programs within ARRL and local ham clubs. It is why Amateur Radio was awarded funds for that purpose from Homeland Security Dept. I don't see none of them thar "expert" chicken band reddio types gittin' any of that money! HAHA! Want laughter? Talk to the Emergency M

anagement folks or Homeland Security or FEMA and tell them how "valuable them chicken banders" and their reddios and leenyars are to them. See how hard they laugh at YOU! You haven't SEEN contempt until you try that.

"HOW 'BOUCHA THAR, THIS H'YAR MOONRAKER IN CENTRAL NAWTH C'LINA, WE TRYIN'! WE'S IS REDDY TO PASS SOME OF THAT EE-MER-GEN-CEE TRAFFIC THAR"

Yeah, right. Your wonderful chicken band radio is full of shit when it comes to real communications. You are dreaming, and your steering wheel and the knowledge contained within its circumference is getting smaller and smaller. Quit while you're ahead.

"Eureka". You're right. This is the way to go. Or at least to try.

Since coax losses don't vary much if at all over any of the individual HF ham bands a decent inline wattmeter with maybe a 4 inch scale should allow me to maintain a constant power output over the sweep.

> Then you do the same thing in software, and tailor the characteristic

can
> model other antennas from that standard.

That's what I need. It'll make a worthwhile weekend project which, if successful, should result in less futzing around with the cutters and the soldering iron up the tower. I'll also compare the experimental results of the bare wire sweeps to the predictions given by the modeler and "calibrate" the modeler in this respect too. Might lead me to my own real world ground condx vs. the generic "real ground" in the modeler which is another big source of modeling non-truths.

I'm sure you have heard of the ARRL Antenna Book also available on
CD. I personally am quite fond of "Antennas For All Applications",
3rd edition, by Kraus and Marhefka. "Antenna Theory" by Balanis is
a very good reference and also my AZ State antennas course textbook
taught by Dr. Balanis himself.

There is no simple response to your question Mike because the ham radio book market is flooded with antenna tomes and we all have different needs, experiences, expectations and preferances when it comes to books on technical topics.

While it's dry and a bit of a trudge take a look at the chapters on antennas in your ARRL handbook for openers. From there the Antenna Book gets into more detail. For my own purposes ON4UN's masterpiece on low-band antennas is a gotta-have. Which you might not give a hoot about. And so forth. If you haven't already done so surf:

http://www.arrl.org/catalog/?category=Antennas%2C+Transmission+Lines+%26+Propagation&words
=

and take yer pick.

Probably the most widely used antenna reference, for good reason, is Kraus' _Antennas_, now in its third edition. If I were limited to a single book, that would be it. You can find used first and second editions at reasonable prices, and they contain solid basic information.

A very complete reference, with deeper discussion of a wide variety of antenna types as well as a moderate amount of basic theory, is Lo and Lee's _Antenna Handbook_ (four volumes). This, however, is likely to be more than you'd want or need as a starter -- and it's relatively expensive.

And no amateur bookshelf should be without the _ARRL Antenna Book_.

Hi Brian,

I left that unsaid, expecting someone, if not you, would also come to that conclusion. It does not work across all bands, but within a band it will suffice. Also, even given the impression of accuracy that most impart to their power meters, this method demands only "relative accuracy" which can be exceptional when care is shown (try to maintain a full scale indication or at least greater than 2/3rds at some cardinal point on the scale).

At this point, one should reflect that if there is a mismatch, then power at the feed point will vary somewhat. In other words, the presumption of constant power (to subtract out the effects of the transmission line) is violated. However, as a first pass estimation, the method is still quite productive, and tightening up the method and the numbers is an exercise left to the experimenter.

For a radio amateur, the ARRL Antenna book is unbeatable. You already have great recommendations. I like them all.

If I had only one book on antennas it would be Terman`s "Electponic and Radio Engineering" which covers not only antennas but whioh covers radio and electronics like a rug. It`s tops for keeping it simple, but not too simple, concise and accurate.

Also, I would be bereft without "Transmission Lines, Antennas, and Wave Guides" by King, Mimno, and Wing. This was a hurry-up WW-2 production to train US Armed Forces Officiers who were assumed to be a little short on prerequisites, so the authors kept it as simple as they could with no sacrifice in accuracuy. It is a gem.

Lotsa of luck in your quest for a good library. My list is by no means complete. Bibliographies in some of the listed ooks have more suggestios.

Best regards, Richard Harrison, KB5WZI

Richard, what do you mean by "If you lack sufficient shielding for the
detector, this will degrade the nulls considerably."

The source is the built in noise generator in the bridge. My detector is my
Icom communications receiver, connected via coax to the bridge.
What additional shielding would be needed??

4595. Re: 31 Mix Beads RFI Suppression (Ignition)?

Newsgroup: rec.radio.amateur.antenna
Date: 2005-03-31 13:05:54 UTC
From: hasan schiers <schiers@netins.net>
Message-ID: <d2gsk2$d41$1@news.netins.net>
Source record: 79840

Hi Richard,

(BTW, I was looking to reduce ignition noise to my D700 in the car, specifically in the VHF region). I have replaced the plugs, cap and rotor. I haven't replaced the ignition wires. I was thinking "chokes" on the wires might do it, but after thinking about it more, and relocating the articles on RFI/EMI suppression wires, it was apparent that no snap-on chokes would work as well as the wires noted below by magnecor.

I now remember (from 10 years ago) what the ignition wires were that were claimed by hams as the best for reducing ignition noise generation. "Magnecor"...as in magnecor.com.

That is what I put in, and they are getting pretty old , 10 years and 198K miles on the car/wires.

Instead of using the 31 mix chokes, I think my money would be better spent getting another set of wires.

In the end, perhaps the only thing that would have helped would have been to buy enough of the snap-on chokes to cover the wires completely, which makes no economic sense.

To the "gentleman" who suggested (without offering any information or responses to my questions) that I buy the chokes, put them on and report back...sorry, I'm not providing information, I'm soliciting it. Your response didn't provide any info, didn't bother to respond to ANY of the questions, and just contained a rather pointless recommendation....if you didn't understand that I wanted someone who "knew" or had thought about the problem to offer an opinion as to the efficacy of 31 mix chokes in this application BEFORE I bothered to buy them, you missed a rather obvious point....duh! This "gentleman" also provides no real name, and no amateur callsign. The typical smart-ass troll.

Thanks to the others (on-list and private), including Richard, who responded. One of the responses led me back to the source of my ten year old wires and how to replace them...I had no idea if the company was still in business or not, nor could I remember their name. They are still there, and I'm going to order a wire-set this morning.

73,

p.s., I might add for learning sake, several of your answers, Richard, beg a "why not". (As in, why doesn't it matter which end, distributor or plug would be more effective, Stacking chokes vs. spacing them out along the wires doesn't matter? Why not?)

Your observation that most modern cars don't have ignition noise is
borderlline laughable for two reasons:

1. It's not true...most in fact do create quite a bit of RFI to HF radios
and some are quite problematic even at two meters.

2. I spend my spare money on radios/antennas and computers, not new
cars...which my '95 Ford Taurus with 198K miles on it testifies to. It is
very well maintained, but old. (and NOISY from an RFI/Ignition point of
view).

Thanks for taking the time to respond. (to all) 73

The closest I've come to owning a murdercycle was when I owned some HD
stock. Unfortunately, I sold it way too soon.

When I was riding my former bro-in-law's big Yamaha and a car pulled
out in front of me and I laid the bike down, I decided I had all the
cycling thrills I needed for a lifetime.

I also lost two ham buddies in the same accident when they were on
their way to Sturgis one year.

Be careful.

It's a little difficult to tell for sure from the photo, but that
tower looks exactly like mine. The whole structure appears to be
exactly the same. It even looks like you have the same tri-bander,
stuck in the middle of the tower.

I don't have the motor on mine, but I secured a large nut on mine so
I can crank it up manually or with a socket in my portable drill.
Anyway, I don't have the data on the tower immediately available, but
I will look it up in the next few days, if you are interested. I
seem to remember that there was some information on the motor drive
unit. Not much, but there may be a manufacturer's name that would help.

This will give me a chance to try out my new scanner.

You seem to skip the "real world" and construct one from the images of your mind, with your text.
Since many "traditional jobs" have and are disappearing, you are NOT unlikely to find a notable number with BS and MS degrees driving a truck!
I have first hand knowledge of this, while I completed my masters thesis in the late 1970's I personally found it a way to add to my income (actually, it may be why I didn't starve to death!) and, an enjoyable one (well, I was smart enough to get my butt OUT of that truck!)
You may have been surprised at the intellects I was able to carry on discourse with who worked in that field.
Yanno, I even able to pick up a southern drawl and blend it with my colleagues in that field--at least verbally, "10-4 good buddy?" You might have heard me back then? (ok, I still sneak on 11 meters and talk like a damn "okie") Perhaps I was/am one of the idiots with poor verbal and written communication skills you are referring to?
In the "major event", many truckers (and yes, everyone in general) will be the true heroes. Like 911 where the common hero went wanting for recognition--the media will devote all of its coverage to such as police, firefighters and authorities--but the unsung heroes will have contributed greatly--you can bet on that.
I imagine some "glory hog(s)" who has been awaiting his chance at his 15 minutes of fame will step forward and some media correspondent will craft a story making him a superman.
But, you know that just the sheer numbers of readily available radios out there will somehow come to use.
Live in your fantasy world, too quick to dismiss the obvious but, always hope these things never come to pass...

>What additional shielding would be needed??

Hi Uwe,

This is entirely revealed by practice. Simply answer how wide is the null? If you don't know how wide it should be, then chances are you don't know how well your system is connected. As I pointed out elsewhere, I can obtain nulls that are 100dB deep. This is one simple measure of width; although not in terms of width, it is very distinctive and correlates with the same consideration. Far more frequently my nulls are 120+dB deep (down into the receiver noise from a signal level of 1mW).

The problem with a noise bridge is power. To observe that same depth of null requires a noise source of several Watts (not sure of the actual figure now, but retail sources don't come close). If you balance your bridge and you run out of signal before you run out of balance, then your settings are at the wrong Z. What appeared to be a balanced null was actually the lack of source power to indicate you were off-set. For a noise bridge, you have to keep adjusting even when the noise seems to have been nulled. You keep going until you find the noise signal climbing again, and then split the difference between the two edges of the silent span of readings. If that is too wide, you could have quite a time of this.

Now, consider if your shielding is not tight and you could hear your source along a path that was not through the bridge = you never hear a null, or you get a very very broad null that still contains noise/signal. A receiver's shielding that is good to -100 to -120dB is exceptional. In our hobby it is not exactly commonplace, but it is found in good equipment. However, how good your equipment is can only be determined through actual testing as shielding is also a function of grounding, and there everyone is an expert but few are well grounded.

>wires doesn't matter? Why not?)

Hi Hasan,

Because the placement is along a very short (in terms of wavelength)
current path. A current path snubbed anywhere is snubbed everywhere.

>Your observation that most modern cars don't have ignition noise is
>borderlline laughable for two reasons:

Those reasons are what we call anecdotal evidence. Anecdotal evidence
may be true to the sufferer, but that does not make it universal.
More the problem, the anecdotal evidence is likely another problem
being described and the evidence misapplied.

The most common source of noise is not the engine electronics
(although this is literally the source); it is in the failure of
grounding and orientation of lead paths. When you look at a car, you
see one huge metal can and think it must be uniformly conducting. The
sad fact is that it is not. Doors and hood and trunk lid are very
common coupling points to the interior as they present very large
capacitive links to the electronics inside. Some manufacturers insure
they are bonded to the frame, others do not. This is all commonplace
"taken for granted" grounding that does not exist and we get
occasional reports of extremely frustrated experimenters who struggle
to only find the hood (the last thing tested) was the culprit.

What keeps automotive electronics (much less their computers and their
own radios) going in the face of this haphazard grounding is that they
have long figured out how to reference all their equipment to the same
potential. This is your problem and you have not found that spot.

That spot appears to be elevated with respect to where you chose to
ground your equipment (or you chose several points and you suffer
ground loops). The noise is being injected by conduction and it is
very hard to snub currents traveling along frame and sheet metal.

If this problem emerged over time, and is found to be ignition wire
specific, then you have also described the same issue. Those wires
were coupling into a path between your ground and the system common.
A simple test:

Does your car's AM/FM radio reveal the same noise on your gear?

Manufacturers make sure this never happens long before they engineer another tenth gallon per mile savings into your car. The difference in the sensitivity between your gear and the car's FM is not very large (if at all).

This antenna went together in about an hour (I took my time) and it plays beautifully at 35ft with a 1.2:1 swr. I also have an M2 Horizontal Loop at 40ft and of course the beam out performs the omni loop but the loop is my main listening antenna for 2M SSB. Also have a Ringo Ranger II up at about 30ft for repeaters and fm mobiles. Pics of all 3 and tech data links at

Source record: 79851

I'm wondering what is the best practice for connecting two transceivers to a single transmission line/antenna, or even if it is advisable to do?

What would be great is if there was a switch that would share the line between the 2 transceivers when no outgoing RF is present, and switch everything to one rig when RF is sensed. However, I haven't seen a product that does this!

thanks for any thoughts,

73,

Chuck

Hi Chuck

In the commercial world usually a circulator is used. It is in fact quite common as the cost of setting up another tower sited antenna is very high.

The big problem with sensing RF is that you are reacting to its presence. Be better to run it from the PTT cct of the TX. I have seen some build it yourself articles for high power PIN diode switches out there. I dont have any URLs but the one I remember was on the LINRAD site - or just do a google on "high power PIN".

Cheers Bob VK2YQA

Hi Bob,

This would separate the two Transceivers, but they would both be deaf.

Circulators are used in frequency split repeaters where the transmit
path and receive path and frequency are different (and further loaded
with cavity filters).

It's amazing how just one comment by a single person got this group into an uproar. I really think that the public in general has a romance with the life of the trucker brought on by the movie and media hype. Truckers are just ordinary people who do an thankless job of moving just about everything there is in North America to and from wholesalers to retailers. Over the years the average trucker's education level has gone from grade school drop outs to men and women holding degrees of various ranges of education. Over the years I've come to know a rather large group of people from a very large slice of various levels of education, similar to that of most truckers. I hold two degrees and a commercial Radio Telephone license, but for some reason I ended up returning to "trucking" all the time. And all the trucks I've driven, over 1 million miles, I've always had my amateur radio(s) and a CB. Each had it's own nicessity and each one had it's own language. On one radio I as a respected amateur radio operator who drove truck, on the other I was just another trucker looking for a traffic report.
Oh, for those who are of the illusion that truckers are the cause of all the terrible accident on the highways, well the only person your fooling is yourself. To get the facts do a little research and you will find that four wheeled vehicles cause more accidents than any other vehicle. Trucks seem to fall into the same catigory as motorcycles do in the public's perseption of the cause of accidents. After you have done your research you will find that both trucks and motorcycles end of up being a very low percentage of the cause of accidents. The only thing the public sees is that when a truck gets into a bad accident it is very bad and devestating distruction. But statistics show there are fewer truck accidents than four wheeled vehicles and there are also far fewer accidents that are caused by trucks entirely. But, this is just this over educated truckers opinion.

Hi Richard,
That last 4 inches of line for a mast is history now. I had purchased a mast mounting kit from M2 but when I installed it I was unable to tune the loop down below about 2:1..so I put the mount away but the swr was erratic during weather and wind. So..I got the bracket back out and looked it over and "voila" I realized I had been mounting the antenna on it incorrectly. Now the bracket works like a charm and all is well.

Eh, I agree with you for the most part - BUT - you "seem" to have missed the
point. "That" "trucker" seemed to be suggesting that the service they
provide sort of entitles them to break the laws. It does NOT. "My" comment
was (not word for word) that if he broke the rules of the road much as he is
suggesting he does of the FCC, then it wouldn't be long or take much to end
the line for him. RULES ARE RULES. LAWS ARE LAWS. Be you a truck driver,
cop, lawyer, politician, doctor, we ALL have laws to live with, if we're to
survive with any sense of common ground. ANY ONE who breaks those rules/laws
is only adding to the problem. "I" know some truckers, I know the job they

do..... I know the sacrifices they make - time away from home and family. "I" am not disputing that. What I was disputing was that person's "holier than thou" approach "since he is a trucker". THAT is what I dismiss..... NOT THE JOB. I was just telling him to come off his high horse, there may come a day when his services are no longer required, then what? HE won't be so high and mighty then. It is guys like that who are the bad apple, and give the rest of you a black eye. Just like a bad cop gives the rest a black eye, a quack doctor does to his/her profession, a politician who takes bribes/steals. ALL give their profession a bad name. Like it or not, every group has them, truckers included. That one stuck his head out to be noticed. He brought attention to himself. Why can't he mutually respect hams and what they have, as he expects the hams to respect him for what he does? It IS a two way street.

There is NO reason he or any of the rest can't do a small bit of studying when laying over at a truck stop or waiting to be loaded, go take an exam, pass it, get a license, then talk with the rest of us who would welcome them. IF they don't want to take an exam, then WHY violate the laws and pick fights with the hams, because they're too damned lazy to do the right thing? It isn't the hams fault. The hams wanted their license, so they did what it took to get it.....

If you intend to defend his approach, then I can't agree with you. As to the rest of what you said, perhaps you're an example they can follow. Maybe "you" can convince them, being one of the bunch. As for "accidents", "I am not a statistician, so I can't say for sure. I could get into the argument regarding bikes, since I ride one as well, but again, without facts to back me up, I'm not going to.

Yea, but it's a real pain having to haul the liquid helium dewar up the
tower in the middle of a dx opening.

That's a beautiful machine, Cecil, but why did it take five minutes to download?

Yes, it does seem that way on the surface, I am sure--an "uproar."
However, I think it more of an effort to finally take those to task, the ones a person usually, and quite willingly, ignores.
It has always been a pet peeve of mine, when someone draws an illusion and encourages me to partake in the enjoyment of it with them; in my past posts, I have responded to them.
I responded to them with a purpose, with patience, with tolerance, and with hope.
They convinced me that they had spouted such verbal babble, perhaps drafted such writings, to the point of where they were/are in grave danger of believing it themselves (it is quite understandable if they seek one gullible enough to believe their tripe), for real. Since few bother to reduce themselves to the levels required to respond with logic or even to devote the time--to insanity--I took pity and did.
The simple/short answer is, "NO ONE IS THAT SPECIAL! Not even you... (well, just possibly me though!)" Just when you begin to think so, a real one shows up--a "certified special" person, and deflates your ego... <frown>
What I see in much of this exchange is a very common phenomena. It is, what seems, a "natural tendency" in human nature, a tendency to think ones-self/themselves "special", above, removed from, of a greater intellect, gifted, endowed by GOD, of possessing a superior reasoning power, more deserving of, an interesting author of, etc, etc, etc...
If we are all silent, what do you think--they will think?

I know, I know, you now will ask, "Who cares?"--and I grant you this point...

Regards

Funny, I go to the web page and it's just antenna stuff, no Harley.
Maybe my ISP is over-protecting me or something...

build a scale model with insulation at 900 MHz and test it on a network analyzer in the lab

remove insulation and retest?

Mark

The question that comes first to my mind is, "Why do you care?"
Certainly an antenna does not need to be resonant to work well. I can
imagine you'd like a reasonably low indicated SWR, just so your
transmitter has a reasonable load to drive.

If you really want to know what's going on at the antenna feedpoint,
you'll need to back the effects of the feedline out of your antenna
analyzer readings, or use an analyzer that does it for you. If you
have a reasonable estimate of the feedline loss and know its electrical
length (easy to find if you put a short at the end of the line and look
at the resulting impedances read on the analyzer), then you should be
able to translate your analyzer readings to actual feedpoint impedance.
Do you have the feedline properly decoupled from the antenna so it's
not a significant part of the radiating system? If not, there seems
little reason to bother making the measurements.

I'd expect half-wave dipole resonance to result in lowest SWR on a
50-ohm feedline, but it won't be a very sharp minimum. So is it worth
worrying about?

Another 'speriment to try: build a fairly wide-spaced two wire
transmission line from your wire. Short it at one end, open at the
other, and look for quarter-wave resonance; or short both ends and look
for half-wave resonance. Measure the resonant frequency, which will be
a pretty sharp resonance (much sharper than the dipole). Remove the
insulation and see how much the resonance changes. Try for various
spacings to see what effect the spacing has. (Expect that close
spacings will show more effect than wide.)

Cheers,
Tom
